IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

About This Manual

This manual discusses modules and peripherals of the MSP430x1xx family of devices. Each discussion presents the module or peripheral in a general sense. Not all features and functions of all modules or peripherals are present on all devices. In addition, modules or peripherals may differ in their exact implementation between device families, or may not be fully implemented on an individual device or device family.

Pin functions, internal signal connections and operational parameters differ from device-to-device. The user should consult the device-specific datasheet for these details.

Related Documentation From Texas Instruments

For related documentation see the web site http://www.ti.com/msp430.

FCC Warning

This equipment is intended for use in a laboratory test environment only. It generates, uses, and can radiate radio frequency energy and has not been tested for compliance with the limits of computing devices pursuant to subpart J of part 15 of FCC rules, which are designed to provide reasonable protection against radio frequency interference. Operation of this equipment in other environments may cause interference with radio communications, in which case the user at his own expense will be required to take whatever measures may be required to correct this interference.

Notational Conventions

Program examples, are shown in a special typeface.

1.1 Architecture

The MSP430 incorporates a 16-bit RISC CPU, peripherals, and a flexible clock system that interconnect using a von-Neumann common memory address bus (MAB) and memory data bus (MDB). Partnering a modern CPU with modular memory-mapped analog and digital peripherals, the MSP430 offers solutions for demanding mixed-signal applications.

Key features of the MSP430x1xx family include:

- Ultralow-power architecture extends battery life
  - 0.1-µA RAM retention
  - 0.8-µA real-time clock mode
  - 250-µA / MIPS active
- High-performance analog ideal for precision measurement
  - 12-bit or 10-bit ADC — 200 ksps, temperature sensor, \( V_{\text{Ref}} \)
  - 12-bit dual-DAC
  - Comparator-gated timers for measuring resistive elements
  - Supply voltage supervisor
- 16-bit RISC CPU enables new applications at a fraction of the code size.
  - Large register file eliminates working file bottleneck
  - Compact core design reduces power consumption and cost
  - Optimized for modern high-level programming
  - Only 27 core instructions and seven addressing modes
  - Extensive vectored-interrupt capability
- In-system programmable Flash permits flexible code changes, field upgrades and data logging

1.2 Flexible Clock System

The clock system is designed specifically for battery-powered applications. A low-frequency auxiliary clock (ACLK) is driven directly from a common 32-kHz watch crystal. The ACLK can be used for a background real-time clock self wake-up function. An integrated high-speed digitally controlled oscillator (DCO) can source the master clock (MCLK) used by the CPU and high-speed peripherals. By design, the DCO is active and stable in less than 6 µs. MSP430-based solutions effectively use the high-performance 16-bit RISC CPU in very short bursts.

- Low-frequency auxiliary clock = Ultralow-power stand-by mode
- High-speed master clock = High performance signal processing
1.3 Embedded Emulation

Dedicated embedded emulation logic resides on the device itself and is accessed via JTAG using no additional system resources.

The benefits of embedded emulation include:

- Unobtrusive development and debug with full-speed execution, breakpoints, and single-steps in an application are supported.
- Development is in-system subject to the same characteristics as the final application.
- Mixed-signal integrity is preserved and not subject to cabling interference.
1.4 Address Space

The MSP430 von-Neumann architecture has one address space shared with special function registers (SFRs), peripherals, RAM, and Flash/ROM memory as shown in Figure 1–2. See the device-specific data sheets for specific memory maps. Code access are always performed on even addresses. Data can be accessed as bytes or words.

The addressable memory space is 64 KB with future expansion planned.

Figure 1–2. Memory Map

1.4.1 Flash/ROM

The start address of Flash/ROM depends on the amount of Flash/ROM present and varies by device. The end address for Flash/ROM is 0FFFFh. Flash can be used for both code and data. Word or byte tables can be stored and used in Flash/ROM without the need to copy the tables to RAM before using them.

The interrupt vector table is mapped into the the upper 16 words of Flash/ROM address space, with the highest priority interrupt vector at the highest Flash/ROM word address (0FFFEh).

1.4.2 RAM

RAM starts at 0200h. The end address of RAM depends on the amount of RAM present and varies by device. RAM can be used for both code and data.
1.4.3 Peripheral Modules

Peripheral modules are mapped into the address space. The address space from 0100 to 01FFh is reserved for 16-bit peripheral modules. These modules should be accessed with word instructions. If byte instructions are used, only even addresses are permissible, and the high byte of the result is always 0.

The address space from 010h to 0FFh is reserved for 8-bit peripheral modules. These modules should be accessed with byte instructions. Read access of byte modules using word instructions results in unpredictable data in the high byte. If word data is written to a byte module only the low byte is written into the peripheral register, ignoring the high byte.

1.4.4 Special Function Registers (SFRs)

Some peripheral functions are configured in the SFRs. The SFRs are located in the lower 16 bytes of the address space, and are organized by byte. SFRs must be accessed using byte instructions only. See the device-specific data sheets for applicable SFR bits.

1.4.5 Memory Organization

Bytes are located at even or odd addresses. Words are only located at even addresses as shown in Figure 1–3. When using word instructions, only even addresses may be used. The low byte of a word is always an even address. The high byte is at the next odd address. For example, if a data word is located at address xxx4h, then the low byte of that data word is located at address xxx4h, and the high byte of that word is located at address xxx5h.

*Figure 1–3. Bits, Bytes, and Words in a Byte-Organized Memory*
This chapter describes the MSP430x1xx system resets, interrupts, and operating modes.

2.1 System Reset and Initialization

The system reset circuitry shown in Figure 2–1 sources both a power-on reset (POR) and a power-up clear (PUC) signal. Different events trigger these reset signals and different initial conditions exist depending on which signal was generated.

Figure 2–1. Power-On Reset and Power-Up Clear Schematic

A POR is a device reset. A POR is only generated by the following two events:

- Powering up the device
- A low signal on the RST/NMI pin when configured in the reset mode
- An SVS low condition when PORON = 1.

A PUC is always generated when a POR is generated, but a POR is not generated by a PUC. The following events trigger a PUC:

- A POR signal
- Watchdog timer expiration when in watchdog mode only
- Watchdog timer security key violation
- A Flash memory security key violation
2.1.1 Power-On Reset (POR)

When the $V_{CC}$ rise time is slow, the POR detector holds the POR signal active until $V_{CC}$ has risen above the $V_{POR}$ level, as shown in Figure 2–2. When the $V_{CC}$ supply provides a fast rise time the POR delay, $t_{(POR\_DELAY)}$, provides active time on the POR signal to allow the MSP430 to initialize.

If power to the MSP430 is cycled, the supply voltage $V_{CC}$ must fall below $V_{min}$ to ensure that another POR signal occurs when $V_{CC}$ is powered up again. If $V_{CC}$ does not fall below $V_{min}$ during a cycle or a glitch, a POR is not generated and power-up conditions do not set correctly. See device-specific datasheet for parameters.

Figure 2–2. POR Timing
2.1.2 Brownout Reset (BOR)

Some devices have a brownout reset circuit (see device-specific datasheet) that replaces the POR detect and POR delay circuits. The brownout reset circuit detects low supply voltages such as when a supply voltage is applied to or removed from the V\textsubscript{CC} terminal. The brownout reset circuit resets the device by triggering a POR signal when power is applied or removed. The operating levels are shown in Figure 2–3.

The POR signal becomes active when V\textsubscript{CC} crosses the V\textsubscript{CC}\textsubscript{(start)} level. It remains active until V\textsubscript{CC} crosses the V\textsubscript{(B\_IT+)} threshold and the delay t\textsubscript{(BOR)} elapses. The delay t\textsubscript{(BOR)} is adaptive being longer for a slow ramping V\textsubscript{CC}. The hysteresis V\textsubscript{hys(B\_IT–)} ensures that the supply voltage must drop below V\textsubscript{(B\_IT–)} to generate another POR signal from the brownout reset circuitry.

*Figure 2–3. Brownout Timing*

As the V\textsubscript{(B\_IT–)} level is significantly above the V\textsubscript{min} level of the POR circuit, the BOR provides a reset for power failures where V\textsubscript{CC} does not fall below V\textsubscript{min}. See device-specific datasheet for parameters.
2.1.3 Device Initial Conditions After System Reset

After a POR, the initial MSP430 conditions are:

- The RST/NMI pin is configured in the reset mode.
- I/O pins are switched to input mode as described in the Digital I/O chapter.
- Other peripheral modules and registers are initialized as described in their respective chapters in this manual.
- Status register (SR) is reset.
- The watchdog timer powers up active in watchdog mode.
- Program counter (PC) is loaded with address contained at reset vector location (0FFFEh). CPU execution begins at that address.

Software Initialization

After a system reset, user software must initialize the MSP430 for the application requirements. The following must occur:

- Initialize the SP, typically to the top of RAM.
- Initialize the watchdog to the requirements of the application.
- Configure peripheral modules to the requirements of the application.

Additionally, the watchdog timer, oscillator fault, and flash memory flags can be evaluated to determine the source of the reset.
2.2 Interrupts

The interrupt priorities are fixed and defined by the arrangement of the modules in the connection chain as shown in Figure 2–4. The nearer a module is to the CPU/NMIRS, the higher the priority. Interrupt priorities determine what interrupt is taken when more than one interrupt is pending simultaneously.

There are three types of interrupts:

- System reset
- (Non)-maskable NMI
- Maskable

Figure 2–4. Interrupt Priority
2.2.1 (Non)-Maskable Interrupts (NMI)

(Non)-maskable NMI interrupts are not masked by the general interrupt enable bit (GIE), but are enabled by individual interrupt enable bits (NMIIE, ACCVIE, OFIE). When a NMI interrupt is accepted, all NMI interrupt enable bits are automatically reset. Program execution begins at the address stored in the (non)-maskable interrupt vector, 0FFFCh. User software must set the required NMI interrupt enable bits for the interrupt to be re-enabled. The block diagram for NMI sources is shown in Figure 2–5.

A (non)-maskable NMI interrupt can be generated by three sources:

- An edge on the RST/NMI pin when configured in NMI mode
- An oscillator fault occurs
- An access violation to the flash memory

Reset/NMI Pin

At power-up, the RST/NMI pin is configured in the reset mode. The function of the RST/NMI pins is selected in the watchdog control register WDTCTL. If the RST/NMI pin is set to the reset function, the CPU is held in the reset state as long as the RST/NMI pin is held low. After the input changes to a high state, the CPU starts program execution at the word address stored in the reset vector, 0FFFEh.

If the RST/NMI pin is configured by user software to the NMI function, a signal edge selected by the NMIES bit generates an NMI interrupt if the NMIIE bit is set. The RST/NMI flag NMIFG is also set.

**Note: Holding RST/NMI Low**

When configured in the NMI mode, a signal generating an NMI event should not hold the RST/NMI pin low. If a PUC occurs from a different source while the NMI signal is low, the device will be held in the reset state because a PUC changes the RST/NMI pin to the reset function.

**Note: Modifying NMIES**

When NMI mode is selected and the NMIES bit is changed, an NMI can be generated, depending on the actual level at the RST/NMI pin. When the NMI edge select bit is changed before selecting the NMI mode, no NMI is generated.
Figure 2–5. Block Diagram of (Non)-Maskable Interrupt Sources
Flash Access Violation

The flash ACCVIFG flag is set when a flash access violation occurs. The flash access violation can be enabled to generate an NMI interrupt by setting the ACCVIE bit. The ACCVIFG flag can then be tested by NMI the interrupt service routine to determine if the NMI was caused by a flash access violation.

Oscillator Fault

The oscillator fault signal warns of a possible error condition with the crystal oscillator. The oscillator fault can be enabled to generate an NMI interrupt by setting the OFIE bit. The OFIFG flag can then be tested by NMI the interrupt service routine to determine if the NMI was caused by an oscillator fault.

A PUC signal can trigger an oscillator fault, because the PUC switches the LFXT1 to LF mode, therefore switching off the HF mode. The PUC signal also switches off the XT2 oscillator.
Example of an NMI Interrupt Handler

The NMI interrupt is a multiple-source interrupt. An NMI interrupt automatically resets the NMIIE, OFIE and ACCVIE interrupt-enable bits. The user NMI service routine resets the interrupt flags and re-enables the interrupt-enable bits according to the application needs as shown in Figure 2–6.

RETI
End of NMI Interrupt Handler

Note: Enabling NMI Interrupts with ACCVIE, NMIIE, and OFIE

The ACCVIE, NMIIE, and OFIE enable bits should not be set inside of an NMI interrupt service routine, unless they are set by the last instruction of the routine before the RETI instruction. Otherwise, nested NMI interrupts may occur, causing stack overflow and unpredictable operation.

2.2.2 Maskable Interrupts

Maskable interrupts are caused by peripherals with interrupt capability including the watchdog timer overflow in interval-timer mode. Each maskable interrupt source can be disabled individually by an interrupt enable bit, or all maskable interrupts can be disabled by the general interrupt enable (GIE) bit in the status register (SR).

Each individual peripheral interrupt is discussed in the associated peripheral module chapter in this manual.
2.2.3 Interrupt Processing

When an interrupt is requested from a peripheral and the peripheral interrupt enable bit and GIE bit are set, the interrupt service routine is requested. Only the individual enable bit must be set for (non)-maskable interrupts to be requested.

Interrupt Acceptance

The interrupt latency is 6 cycles, starting with the acceptance of an interrupt request, and lasting until the start of execution of the first instruction of the interrupt-service routine, as shown in Figure 2–7. The interrupt logic executes the following:

1) Any currently executing instruction is completed.
2) The PC, which points to the next instruction, is pushed onto the stack.
3) The SR is pushed onto the stack.
4) The interrupt with the highest priority is selected if multiple interrupts occurred during the last instruction and are pending for service.
5) The interrupt request flag resets automatically on single-source flags. Multiple source flags remain set for servicing by software.
6) The SR is cleared with the exception of SCG0, which is left unchanged. This terminates any low-power mode. Because the GIE bit is cleared, further interrupts are disabled.
7) The content of the interrupt vector is loaded into the PC: the program continues with the interrupt service routine at that address.

*Figure 2–7. Interrupt Processing*
Return From Interrupt

The interrupt handling routine terminates with the instruction:

\textbf{RETI} \textit{(return from an interrupt service routine)}

The return from the interrupt takes 5 cycles to execute the following actions and is illustrated in Figure 2–8.

1) The SR with all previous settings pops from the stack. All previous settings of GIE, CPUOFF, etc. are now in effect, regardless of the settings used during the interrupt service routine.

2) The PC pops from the stack and begins execution at the point where it was interrupted.

\textit{Figure 2–8. Return From Interrupt}

![Diagram of Return From Interrupt]

Interrupt Nesting

Interrupt nesting is enabled if the GIE bit is set inside an interrupt service routine. When interrupt nesting is enabled, any interrupt occurring during an interrupt service routine will interrupt the routine, regardless of the interrupt priorities.
2.2.4 Interrupt Vectors

The interrupt vectors and the power-up starting address are located in the address range 0xFFFFh – 0xFFE0h as described in Table 2–1. A vector is programmed by the user with the 16-bit address of the corresponding interrupt service routine. See the device-specific data sheet for the complete interrupt vector list.

Some module enable bits, interrupt enable bits, and interrupt flags are located in the SFRs. The SFRs are located in the lower address range and are implemented in byte format. SFRs must be accessed using byte instructions. See the device-specific datasheet for the SFR configuration.
2.3 Operating Modes

The MSP430 family is designed for ultralow-power applications and uses different operating modes shown in Figure 2–10.

The operating modes take into account three different needs:

- Ultralow-power
- Speed and data throughput
- Minimization of individual peripheral current consumption

The MSP430 typical current consumption is shown in Figure 2–9.

Figure 2–9. Typical Current Consumption of 13x and 14x Devices vs Operating Modes

![Typical Current Consumption Graph]

The low-power modes 0–4 are configured with the CPUOFF, OSCOFF, SCG0, and SCG1 bits in the status register. The advantage of including the CPUOFF, OSCOFF, SCG0, and SCG1 mode-control bits in the status register is that the present operating mode is saved onto the stack during an interrupt service routine. Program flow returns to the previous operating mode if the saved SR value is not altered during the interrupt service routine. Program flow can be returned to a different operating mode by manipulating the saved SR value on the stack inside of the interrupt service routine. The mode-control bits and the stack can be accessed with any instruction.

When setting any of the mode-control bits, the selected operating mode takes effect immediately. Peripherals operating with any disabled clock are disabled until the clock becomes active. The peripherals may also be disabled with their individual control register settings. All I/O port pins and RAM/registers are unchanged. Wake up is possible through all enabled interrupts.

</table>
2.3.1 Entering and Exiting Low-Power Modes

An enabled interrupt event wakes the MSP430 from any of the low-power operating modes. The program flow is:

- Enter interrupt service routine:
  - The PC and SR are stored on the stack
  - The CPUOFF, SCG1, and OSCOFF bits are automatically reset

- Options for returning from the interrupt service routine:
  - The original SR is popped from the stack, restoring the previous operating mode.
  - The SR bits stored on the stack can be modified within the interrupt service routine returning to a different operating mode when the RETI instruction is executed.

```
; Enter LPM0 Example
BIS #GIE+CPUOFF,SR ; Enter LPM0
; ... ; Program stops here
;
; Exit LPM0 Interrupt Service Routine
BIC #CPUOFF,0(SP) ; Exit LPM0 on RETI
RETI

; Enter LPM3 Example
BIS #GIE+CPUOFF+SCG1+SCG0,SR ; Enter LPM3
; ... ; Program stops here
;
; Exit LPM3 Interrupt Service Routine
BIC #CPUOFF+SCG1+SCG0,0(SP) ; Exit LPM3 on RETI
RETI
```

Extended Time in Low-Power Modes

The negative temperature coefficient of the DCO should be considered when the DCO is disabled for extended low-power mode periods. If the temperature changes significantly, the DCO frequency at wake-up may be significantly different from when the low-power mode was entered and may be out of the specified operating range. To avoid this, the DCO can be set to it lowest value before entering the low-power mode for extended periods of time where temperature can change.

```
; Enter LPM4 Example with lowest DCO Setting
BIC #RSEL2+RSEL1+RSEL0,&BCSCTL1 ; Lowest RSEL
BIS #GIE+CPUOFF+OSCOFF+SCG1+SCG0,SR ; Enter LPM4
; ... ; Program stops here
;
; Interrupt Service Routine
BIC #CPUOFF+OSCOFF+SCG1+SCG0,0(SR); Exit LPM4 on RETI
RETI
```
2.4 Principles for Low-Power Applications

Often, the most important factor for reducing power consumption is using the MSP430’s clock system to maximize the time in LPM3. LPM3 power consumption is less than 2 \( \mu \text{A} \) typical with both a real-time clock function and all interrupts active. A 32-kHz watch crystal is used for the ACLK and the CPU is clocked from the DCO (normally off) which has a 6-\( \mu \text{s} \) wake-up.

- Use interrupts to wake the processor and control program flow.
- Peripherals should be switched on only when needed.
- Use low-power integrated peripheral modules in place of software driven functions. For example Timer_A and Timer_B can automatically generate PWM and capture external timing, with no CPU resources.
- Calculated branching and fast table look-ups should be used in place of flag polling and long software calculations.
- Avoid frequent subroutine and function calls due to overhead.
- For longer software routines, single-cycle CPU registers should be used.

2.5 Connection of Unused Pins

The correct termination of all unused pins is listed in Table 2–2.

3.1 CPU Introduction

The CPU incorporates features specifically designed for modern programming techniques such as calculated branching, table processing and the use of high-level languages such as C. The CPU can address the complete address range without paging.

The CPU features include:

- RISC architecture with 27 instructions and 7 addressing modes.
- Orthogonal architecture with every instruction usable with every addressing mode.
- Full register access including program counter, status registers, and stack pointer.
- Single-cycle register operations.
- Large 16-bit register file reduces fetches to memory.
- 16-bit address bus allows direct access and branching throughout entire memory range.
- 16-bit data bus allows direct manipulation of word-wide arguments.
- Constant generator provides six most used immediate values and reduces code size.
- Direct memory-to-memory transfers without intermediate register holding.
- Word and byte addressing and instruction formats.

The block diagram of the CPU is shown in Figure 3–1.

3.2 CPU Registers

The CPU incorporates sixteen 16-bit registers. R0, R1, R2 and R3 have dedicated functions. R4 to R15 are working registers for general use.

3.2.1 Program Counter (PC)

The 16-bit program counter (PC/R0) points to the next instruction to be executed. Each instruction uses an even number of bytes (two, four, or six), and the PC is incremented accordingly. Instruction accesses in the 64-KB address space are performed on word boundaries, and the PC is aligned to even addresses. Figure 3–2 shows the program counter.

Figure 3–2. Program Counter

<table>

</table>

The PC can be addressed with all instructions and addressing modes. A few examples:

MOV #LABEL, PC ; Branch to address LABEL
MOV LABEL, PC ; Branch to address contained in LABEL
MOV @R14, PC ; Branch indirect to address in R14
3.2.2 Stack Pointer (SP)

The stack pointer (SP/R1) is used by the CPU to store the return addresses of subroutine calls and interrupts. It uses a predecrement, postincrement scheme. In addition, the SP can be used by software with all instructions and addressing modes. Figure 3-3 shows the SP. The SP is initialized into RAM by the user, and is aligned to even addresses.

Figure 3-4 shows stack usage.

</tr>
</tbody>
</table>

The special cases of using the SP as an argument to the PUSH and POP instructions are described and shown in Figure 3-5.

Figure 3-5. PUSH SP - POP SP Sequence

The stack pointer is changed after a PUSH SP instruction. The POP SP instruction places SP1 into the stack pointer SP (SP2=SP1)
3.2.3 Status Register (SR)

The status register (SR/R2), used as a source or destination register, can be used in the register mode only addressed with word instructions. The remaining combinations of addressing modes are used to support the constant generator. Figure 3–6 shows the SR bits.

Figure 3–6. Status Register Bits

Table 3–1 describes the status register bits.

Table 3–1. Description of Status Register Bits

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
</table>
| V   | Overflow bit. This bit is set when the result of an arithmetic operation overflows the signed-variable range. Set when:  
\( \text{ADD}(.B), \text{ADDC}(.B) \)  
Positive + Positive = Negative  
Negative + Negative = Positive, otherwise reset  
\( \text{SUB}(.B), \text{SUBC}(.B), \text{CMP}(.B) \)  
Set when:  
Positive – Negative = Negative  
Negative – Positive = Positive, otherwise reset |
| SCG1 | System clock generator 1. This bit, when set, turns off the SMCLK. |
| SCG0 | System clock generator 0. This bit, when set, turns off the DCO dc generator, if DCOCLK is not used for MCLK or SMCLK. |
| OSCOFF | Oscillator Off. This bit, when set, turns off the LFXT1 crystal oscillator, when LFXT1CLK is not use for MCLK or SMCLK |
| CPUOFF | CPU off. This bit, when set, turns off the CPU. |
| GIE | General interrupt enable. This bit, when set, enables maskable interrupts. When reset, all maskable interrupts are disabled. |
| N  | Negative bit. This bit is set when the result of a byte or word operation is negative and cleared when the result is not negative.  
Word operation:  
\( N \) is set to the value of bit 15 of the result  
Byte operation:  
\( N \) is set to the value of bit 7 of the result |
| Z  | Zero bit. This bit is set when the result of a byte or word operation is 0 and cleared when the result is not 0. |
| C  | Carry bit. This bit is set when the result of a byte or word operation produced a carry and cleared when no carry occurred. |
3.2.4 Constant Generator Registers CG1 and CG2

Six commonly-used constants are generated with the constant generator registers R2 and R3, without requiring an additional 16-bit word of program code. The constants are selected with the source-register addressing modes (As), as described in Table 3–2.

Table 3–2. Values of Constant Generators CG1, CG2

</tbody>
</table>

The constant generator advantages are:

- No special instructions required
- No additional code word for the six constants
- No code memory access required to retrieve the constant

The assembler uses the constant generator automatically if one of the six constants is used as an immediate source operand. Registers R2 and R3, used in the constant mode, cannot be addressed explicitly; they act as source-only registers.

Constant Generator – Expanded Instruction Set

The RISC instruction set of the MSP430 has only 27 instructions. However, the constant generator allows the MSP430 assembler to support 24 additional, emulated instructions. For example, the single-operand instruction:

```
CLR  dst
```

is emulated by the double-operand instruction with the same length:

```
MOV  R3,dst
```

where the #0 is replaced by the assembler, and R3 is used with As=00.

```
INC  dst
```

is replaced by:

```
ADD  0(R3),dst
```
3.2.5 General–Purpose Registers R4 - R15

The twelve registers, R4–R15, are general-purpose registers. All of these registers can be used as data registers, address pointers, or index values and can be accessed with byte or word instructions as shown in Figure 3–7.

Figure 3–7. Register-Byte/Byte-Register Operations

<table>
<thead>
<tr>
<th>Example Register-Byte Operation</th>
<th>Example Byte-Register Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>R5 = 0A28Fh</td>
<td>R5 = 01202h</td>
</tr>
<tr>
<td>R6 = 0203h</td>
<td>R6 = 0223h</td>
</tr>
<tr>
<td>Mem(0203h) = 012h</td>
<td>Mem(0223h) = 05Fh</td>
</tr>
</tbody>
</table>

**Register-Byte Operation**

<table>
<thead>
<tr>
<th>High Byte</th>
<th>Low Byte</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unused</td>
<td>Register</td>
</tr>
</tbody>
</table>

**Byte-Register Operation**

<table>
<thead>
<tr>
<th>High Byte</th>
<th>Low Byte</th>
</tr>
</thead>
<tbody>
<tr>
<td>0h</td>
<td>Register</td>
</tr>
</tbody>
</table>

**Example Register-Byte Operation**

\[
\begin{align*}
\text{ADD . B} & \quad \text{R5, 0 (R6)} \\
08Fh & + 012h \\
\hline
0A1h & \\
\end{align*}
\]

Mem (0203h) = 0A1h
C = 0, Z = 0, N = 1

**Example Byte-Register Operation**

\[
\begin{align*}
\text{ADD . B} & \quad \text{0R6, R5} \\
05Fh & + 002h \\
\hline
00061h & \\
\end{align*}
\]

R5 = 00061h
C = 0, Z = 0, N = 0

(Low byte of register) + (Addressed byte) -> (Addressed byte)

(Low byte of register, zero to High byte)
3.3 Addressing Modes

Seven addressing modes for the source operand and four addressing modes for the destination operand can address the complete address space with no exceptions. The bit numbers in Table 3–3 describe the contents of the As (source) and Ad (destination) mode bits.

Table 3–3. Source/Destination Operand Addressing Modes

<table>
<thead>
<tr>
<th>As/Ad</th>
<th>Addressing Mode</th>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00/0</td>
<td>Register mode</td>
<td>Rn</td>
<td>Register contents are operand</td>
</tr>
<tr>
<td>01/1</td>
<td>Indexed mode</td>
<td>X(Rn)</td>
<td>(Rn + X) points to the operand. X is stored in the next word.</td>
</tr>
<tr>
<td>01/1</td>
<td>Symbolic mode</td>
<td>ADDR</td>
<td>(PC + X) points to the operand. X is stored in the next word. Indexed mode X(PC) is used.</td>
</tr>
<tr>
<td>01/1</td>
<td>Absolute mode</td>
<td>&amp;ADDR</td>
<td>The word following the instruction contains the absolute address. X is stored in the next word. Indexed mode X(SR) is used.</td>
</tr>
<tr>
<td>10/–</td>
<td>Indirect register mode</td>
<td>@Rn</td>
<td>Rn is used as a pointer to the operand.</td>
</tr>
<tr>
<td>11/–</td>
<td>Indirect autoincrement</td>
<td>@Rn+</td>
<td>Rn is used as a pointer to the operand. Rn is incremented afterwards by 1 for .B instructions and by 2 for .W instructions.</td>
</tr>
<tr>
<td>11/–</td>
<td>Immediate mode</td>
<td>#N</td>
<td>The word following the instruction contains the immediate constant N. Indirect autoincrement mode @PC+ is used.</td>
</tr>
</tbody>
</table>

The seven addressing modes are explained in detail in the following sections. Most of the examples show the same addressing mode for the source and destination, but any valid combination of source and destination addressing modes is possible in an instruction.

**Note:** Use of Labels EDE, TONI, TOM, and LEO

Throughout MSP430 documentation EDE, TONI, TOM, and LEO are used as generic labels. They are only labels. They have no special meaning.
3.3.1 Register Mode

The register mode is described in Table 3–4.

Table 3–4. Register Mode Description

<table>
<thead>
<tr>
<th>Assembler Code</th>
<th>Content of ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV R10,R11</td>
<td>MOV R10,R11</td>
</tr>
</tbody>
</table>

Length: One or two words
Operation: Move the content of R10 to R11. R10 is not affected.
Comment: Valid for source and destination
Example: MOV R10,R11

Before: | After: |
---|---|
R10 | R10 |
0A023h | 0A023h |
R11 | R11 |
0FA15h | 0A023h |
PC | PC |
PC<sub>old</sub> | PC<sub>old + 2</sub> |

Note: Data in Registers
The data in the register can be accessed using word or byte instructions. If byte instructions are used, the high byte is always 0 in the result. The status bits are handled according to the result of the byte instruction.
### 3.3.2 Indexed Mode

The indexed mode is described in Table 3–5.

**Table 3–5. Indexed Mode Description**

<table>
<thead>
<tr>
<th>Assembler Code</th>
<th>Content of ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV 2 (R5), 6 (R6)</td>
<td>MOV X (R5), Y (R6)</td>
</tr>
<tr>
<td>X = 2</td>
<td>Y = 6</td>
</tr>
</tbody>
</table>

Length: Two or three words

Operation: Move the contents of the source address (contents of R5 + 2) to the destination address (contents of R6 + 6). The source and destination registers (R5 and R6) are not affected. In indexed mode, the program counter is incremented automatically so that program execution continues with the next instruction.

Comment: Valid for source and destination

Example: MOV 2 (R5), 6 (R6);

<table>
<thead>
<tr>
<th>Address Space</th>
<th>Register</th>
<th>After</th>
<th>Address Space</th>
<th>Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>0FF16h</td>
<td>00006h</td>

<td>05555h</td>
<td>01092h</td>
<td>010234h</td>
<td>01092h</td>
</tr>
<tr>
<td>01090h</td>
<td>0xxxxh</td>
<td>01090h</td>
<td>0xxxxh</td>
<td>01090h</td>
</tr>
<tr>
<td>01084h</td>
<td>0xxxxh</td>
<td>01080h</td>
<td>+0002h</td>
<td>01084h</td>
</tr>
<tr>
<td>01082h</td>
<td>01234h</td>
<td>01082h</td>
<td>01234h</td>
<td>01082h</td>
</tr>
<tr>
<td>01080h</td>
<td>0xxxxh</td>
<td>01080h</td>
<td>0xxxxh</td>
<td>01080h</td>
</tr>
</tbody>
</table>
3.3.3 Symbolic Mode

The symbolic mode is described in Table 3-6.

Table 3-6. Symbolic Mode Description

<table>
<thead>
<tr>
<th>Assembler Code</th>
<th>Content of ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV EDE,TONI</td>
<td>MOV X(PC),Y(PC)</td>
</tr>
<tr>
<td>X = EDE – PC</td>
<td>Y = TONI – PC</td>
</tr>
</tbody>
</table>

Length: Two or three words

Operation: Move the contents of the source address EDE (contents of PC + X) to the destination address TONI (contents of PC + Y). The words after the instruction contain the differences between the PC and the source or destination addresses. The assembler computes and inserts offsets X and Y automatically. With symbolic mode, the program counter (PC) is incremented automatically so that program execution continues with the next instruction.

Comment: Valid for source and destination

Example: MOV EDE,TONI ;Source address EDE = 0F016h ;Dest. address TONI=01114h

Before: Address Space | Register | After: Address Space | Register |
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0FF16h</td>
<td>011FEh</td>
<td>0FF16h</td>
<td>011FEh</td>
</tr>
<tr>
<td>0FF14h</td>
<td>0F102h</td>
<td>0FF14h</td>
<td>0F102h</td>
</tr>
<tr>
<td>0FF12h</td>
<td>04090h</td>
<td>0FF12h</td>
<td>04090h</td>
</tr>
</tbody>
</table>

| 0F018h               | 0xxxxh   | 0F102h               | 0F018h   |
| 0F016h               | 0123h    | 0F016h               | 0F016h   |
| 0F014h               | 0xxxxh   | 0F014h               | 0xxxxh   |

| 01116h               | 0xxxxh   | 0F16h                | 01116h   |
| 01114h               | 05555h   | 01114h               | 0A123h   |
| 01112h               | 0xxxxh   | 01112h               | 0xxxxh   |
3.3.4 Absolute Mode

The absolute mode is described in Table 3-7.

Table 3-7. Absolute Mode Description

<table>
<thead>
<tr>
<th>Assembler Code</th>
<th>Content of ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV &amp;EDE,&amp;TONI</td>
<td>MOV X(0),Y(0)</td>
</tr>
<tr>
<td>X = EDE</td>
<td>Y = TONI</td>
</tr>
</tbody>
</table>

Length: Two or three words

Operation: Move the contents of the source address EDE to the destination address TONI. The words after the instruction contain the absolute address of the source and destination addresses. With absolute mode, the PC is incremented automatically so that program execution continues with the next instruction.

Comment: Valid for source and destination

Example: MOV &EDE,&TONI ;Source address EDE=0F016h, ;dest. address TONI=01114h

This address mode is mainly for hardware peripheral modules that are located at an absolute, fixed address. These are addressed with absolute mode to ensure software transportability (for example, position-independent code).
### 3.3.5 Indirect Register Mode

The indirect register mode is described in Table 3–8.

#### Table 3–8. Indirect Mode Description

<table>
<thead>
<tr>
<th>Assembler Code</th>
<th>Content of ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV @R10, 0(R11)</td>
<td>MOV @R10, 0(R11)</td>
</tr>
</tbody>
</table>

**Length:** One or two words

**Operation:** Move the contents of the source address (contents of R10) to the destination address (contents of R11). The registers are not modified.

**Comment:** Valid only for source operand. The substitute for destination operand is 0(Rd).

**Example:** MOV.B @R10, 0(R11)

<table>
<thead>
<tr>
<th>Before:</th>
<th>Address Space</th>
<th>Register</th>
<th>After:</th>
<th>Address Space</th>
<th>Register</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0FF16h</td>
<td>0000h</td>
<td>R10 0FA33h</td>
<td>0FF16h</td>
<td>0000h</td>
</tr>
<tr>
<td></td>
<td>0FF14h</td>
<td>04AEBh</td>
<td>PC R11 02A7h</td>
<td>0FF14h</td>
<td>04AEBh</td>
</tr>
<tr>
<td></td>
<td>0FF12h</td>
<td>0xxxxh</td>
<td>0FF12h</td>
<td>0xxxxh</td>
<td></td>
</tr>
<tr>
<td></td>
<td>0FA34h</td>
<td>0xxxxh</td>
<td>0FA34h</td>
<td>0xxxxh</td>
<td></td>
</tr>
<tr>
<td></td>
<td>0FA32h</td>
<td>05BC1h</td>
<td>0FA32h</td>
<td>05BC1h</td>
<td></td>
</tr>
<tr>
<td></td>
<td>0FA30h</td>
<td>0xxxxh</td>
<td>0FA30h</td>
<td>0xxxxh</td>
<td></td>
</tr>
<tr>
<td></td>
<td>002A8h</td>
<td>0xxh</td>
<td>002A8h</td>
<td>0xxh</td>
<td></td>
</tr>
<tr>
<td></td>
<td>002A7h</td>
<td>012h</td>
<td>002A7h</td>
<td>05Bh</td>
<td></td>
</tr>
<tr>
<td></td>
<td>002A6h</td>
<td>0xxh</td>
<td>002A6h</td>
<td>0xxh</td>
<td></td>
</tr>
</tbody>
</table>
3.3.6 Indirect Autoincrement Mode

The indirect autoincrement mode is described in Table 3–9.

Table 3–9. Indirect Autoincrement Mode Description

<table>
<thead>
<tr>
<th>Assembler Code</th>
<th>Content of ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV @R10+, 0(R11)</td>
<td>MOV @R10+, 0(R11)</td>
</tr>
</tbody>
</table>

Length: One or two words

Operation: Move the contents of the source address (contents of R10) to the destination address (contents of R11). Register R10 is incremented by 1 for a byte operation, or 2 for a word operation after the fetch; it points to the next address without any overhead. This is useful for table processing.

Comment: Valid only for source operand. The substitute for destination operand is 0(Rd) plus second instruction INCD Rd.

Example: MOV @R10+, 0(R11)

Before:

<table>
<thead>
<tr>
<th>Address Space</th>
<th>Register</th>
<th>After: Address Space</th>
<th>Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>0FF18h</td>
<td>0xxxxh</td>
<td>0FF18h</td>
<td>0xxxxh</td>
</tr>
<tr>
<td>0FF16h</td>
<td>00000h</td>
<td>R10</td>
<td>0FF16h</td>
</tr>
<tr>
<td>0FF14h</td>
<td>04ABBh</td>
<td>PC</td>
<td>0FF14h</td>
</tr>
<tr>
<td>0FF12h</td>
<td>0xxxxh</td>
<td>0FF12h</td>
<td>0xxxxh</td>
</tr>
</tbody>
</table>

0FA34h 0xxxxh 0FA34h 0xxxxh
0FA32h 05BC1h 0FA32h 05BC1h
0FA30h 0xxxxh 0FA30h 0xxxxh
010AAh 0xxxxh 010AAh 0xxxxh
010A8h 01234h 010A8h 05BC1h
010A6h 0xxxxh 010A6h 0xxxxh

The autoincrementing of the register contents occurs after the operand is fetched. This is shown in Figure 3–8.

Figure 3–8. Operand Fetch Operation

Instruction → Address → Operand

+1/ +2
3.3.7 Immediate Mode

The immediate mode is described in Table 3–10.

Table 3–10. Immediate Mode Description

<table>
<thead>
<tr>
<th>Assembler Code</th>
<th>Content of ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV #45h, TONI</td>
<td>MOV @PC+, X(PC)</td>
</tr>
<tr>
<td></td>
<td>45</td>
</tr>
<tr>
<td></td>
<td>X = TONI – PC</td>
</tr>
</tbody>
</table>

Length: Two or three words
It is one word less if a constant of CG1 or CG2 can be used.

Operation: Move the immediate constant 45h, which is contained in the word following the instruction, to destination address TONI. When fetching the source, the program counter points to the word following the instruction and moves the contents to the destination.

Comment: Valid only for a source operand.

Example: MOV #45h, TONI

<table>
<thead>
<tr>
<th>Before: Address Space</th>
<th>Register</th>
<th>After: Address Space</th>
<th>Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>0FF16h</td>
<td>01192h</td>
<td>0FF16h</td>
<td>01192h</td>
</tr>
<tr>
<td>0FF14h</td>
<td>00045h</td>
<td>0FF14h</td>
<td>00045h</td>
</tr>
<tr>
<td>0FF12h</td>
<td>040B0h</td>
<td>0FF12h</td>
<td>040B0h</td>
</tr>
<tr>
<td>010A8h</td>
<td>0xxxxh</td>
<td>010A8h</td>
<td>0xxxxh</td>
</tr>
<tr>
<td>010A6h</td>
<td>0xxxxh</td>
<td>010A6h</td>
<td>0xxxxh</td>
</tr>
</tbody>
</table>
## 3.4 Instruction Set

The complete MSP430 instruction set consists of 27 core instructions and 24 emulated instructions. The core instructions are instructions that have unique op-codes decoded by the CPU. The emulated instructions are instructions that make code easier to write and read, but do not have op-codes themselves, instead they are replaced automatically by the assembler with an equivalent core instruction. There is no code or performance penalty for using emulated instruction.

There are three core-instruction formats:

- Dual-operand
- Single-operand
- Jump

All single-operand and dual-operand instructions can be byte or word instructions by using .B or .W extensions. Byte instructions are used to access byte data or byte peripherals. Word instructions are used to access word data or word peripherals. If no extension is used, the instruction is a word instruction.

The source and destination of an instruction are defined by the following fields:

<table>
<thead>
<tr>
<th>src</th>
<th>The source operand defined by As and S-reg</th>
</tr>
</thead>
<tbody>
<tr>
<td>dst</td>
<td>The destination operand defined by Ad and D-reg</td>
</tr>
<tr>
<td>As</td>
<td>The addressing bits responsible for the addressing mode used for the source (src)</td>
</tr>
<tr>
<td>S-reg</td>
<td>The working register used for the source (src)</td>
</tr>
<tr>
<td>Ad</td>
<td>The addressing bits responsible for the addressing mode used for the destination (dst)</td>
</tr>
<tr>
<td>D-reg</td>
<td>The working register used for the destination (dst)</td>
</tr>
<tr>
<td>B/W</td>
<td>Byte or word operation:</td>
</tr>
<tr>
<td></td>
<td>0: word operation</td>
</tr>
<tr>
<td></td>
<td>1: byte operation</td>
</tr>
</tbody>
</table>

### Note: Destination Address

Destination addresses are valid anywhere in the memory map. However, when using an instruction that modifies the contents of the destination, the user must ensure the destination address is writable. For example, a masked-ROM location would be a valid destination address, but the contents are not modifiable, so the results of the instruction would be lost.
3.4.1 Double-Operand (Format I) Instructions

Figure 3–9 illustrates the double-operand instruction format.

Figure 3–9. Double Operand Instruction Format

Table 3–11 lists and describes the double operand instructions.

Table 3–11. Double Operand Instructions

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>S-Reg, Operation</th>
<th>Status Bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV (.B)</td>
<td>src, dst, src → dst</td>
<td>– – – –</td>
</tr>
<tr>
<td>ADD (.B)</td>
<td>src, dst, src + dst → dst</td>
<td>* * * *</td>
</tr>
<tr>
<td>ADC (.B)</td>
<td>src, dst, src + dst + C → dst</td>
<td>* * * *</td>
</tr>
<tr>
<td>SUB (.B)</td>
<td>src, dst, dst + .not.src + 1 → dst</td>
<td>* * * *</td>
</tr>
<tr>
<td>SBC (.B)</td>
<td>src, dst, dst + .not.src + C → dst</td>
<td>* * * *</td>
</tr>
<tr>
<td>CMP (.B)</td>
<td>src, dst, dst – src</td>
<td>* * * *</td>
</tr>
<tr>
<td>DADD (.B)</td>
<td>src, dst, src + dst + C → dst (decimally)</td>
<td>* * * *</td>
</tr>
<tr>
<td>BIT (.B)</td>
<td>src, dst, src .and. dst</td>
<td>0 * * *</td>
</tr>
<tr>
<td>BIC (.B)</td>
<td>src, dst, .not.src .and. dst → dst</td>
<td>– – – –</td>
</tr>
<tr>
<td>BIS (.B)</td>
<td>src, dst, src .or. dst → dst</td>
<td>– – – –</td>
</tr>
<tr>
<td>XOR (.B)</td>
<td>src, dst, src .xor. dst → dst</td>
<td>* * * *</td>
</tr>
<tr>
<td>AND (.B)</td>
<td>src, dst, src .and. dst → dst</td>
<td>0 * * *</td>
</tr>
</tbody>
</table>

* The status bit is affected
– The status bit is not affected
0 The status bit is cleared
1 The status bit is set

Note: Instructions CMP and SUB

The instructions CMP and SUB are identical except for the storage of the result. The same is true for the BIT and AND instructions.
3.4.2 Single-Operand (Format II) Instructions

Figure 3–10 illustrates the single-operand instruction format.

**Figure 3–10. Single Operand Instruction Format**

![Figure 3–10. Single Operand Instruction Format](image)

Table 3–12 lists and describes the single operand instructions.

**Table 3–12. Single Operand Instructions**

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>S-Reg, D-Reg</th>
<th>Operation</th>
<th>Status Bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>RRC(.B)</td>
<td>dst</td>
<td>C → MSB → ......LSB → C</td>
<td>* * * *</td>
</tr>
<tr>
<td>RRA(.B)</td>
<td>dst</td>
<td>MSB → MSB → ......LSB → C</td>
<td>0 * * *</td>
</tr>
<tr>
<td>PUSH(.B)</td>
<td>src</td>
<td>SP − 2 → SP, src → @SP</td>
<td>– – – –</td>
</tr>
<tr>
<td>SWPB</td>
<td>dst</td>
<td>Swap bytes</td>
<td>– – – –</td>
</tr>
<tr>
<td>CALL</td>
<td>dst</td>
<td>SP − 2 → SP, PC+2 → @SP</td>
<td>– – – –</td>
</tr>
<tr>
<td></td>
<td></td>
<td>dst → PC</td>
<td></td>
</tr>
<tr>
<td>RETI</td>
<td></td>
<td>TOS → SR, SP + 2 → SP</td>
<td>* * * *</td>
</tr>
<tr>
<td></td>
<td></td>
<td>TOS → PC, SP + 2 → SP</td>
<td></td>
</tr>
<tr>
<td>SXT</td>
<td>dst</td>
<td>Bit 7 → Bit 8 ...... Bit 15</td>
<td>0 * * *</td>
</tr>
</tbody>
</table>

* The status bit is affected
– The status bit is not affected
0 The status bit is cleared
1 The status bit is set

All addressing modes are possible for the CALL instruction. If the symbolic mode (ADDRESS), the immediate mode (#N), the absolute mode (&EDE) or the indexed mode x(RN) is used, the word that follows contains the address information.
3.4.3 Jumps

Figure 3–11 shows the conditional-jump instruction format.

Figure 3–11. Jump Instruction Format

![Figure 3–11. Jump Instruction Format](image)

Table 3–13 lists and describes the jump instructions.

Table 3–13. Jump Instructions

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>S-Reg, D-Reg</th>
<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>JEQ/JZ</td>
<td>Label</td>
<td>Jump to label if zero bit is set</td>
</tr>
<tr>
<td>JNE/JNZ</td>
<td>Label</td>
<td>Jump to label if zero bit is reset</td>
</tr>
<tr>
<td>JC</td>
<td>Label</td>
<td>Jump to label if carry bit is set</td>
</tr>
<tr>
<td>JNC</td>
<td>Label</td>
<td>Jump to label if carry bit is reset</td>
</tr>
<tr>
<td>JN</td>
<td>Label</td>
<td>Jump to label if negative bit is set</td>
</tr>
<tr>
<td>JGE</td>
<td>Label</td>
<td>Jump to label if (N .XOR. V) = 0</td>
</tr>
<tr>
<td>JL</td>
<td>Label</td>
<td>Jump to label if (N .XOR. V) = 1</td>
</tr>
<tr>
<td>JMP</td>
<td>Label</td>
<td>Jump to label unconditionally</td>
</tr>
</tbody>
</table>

Conditional jumps support program branching relative to the PC and do not affect the status bits. The possible jump range is from $-511$ to $+512$ words relative to the PC value at the jump instruction. The 10-bit program-counter offset is treated as a signed 10-bit value that is doubled and added to the program counter:

$$PC_{\text{new}} = PC_{\text{old}} + 2 + PC_{\text{offset}} \times 2$$
ADC[.W]  Add carry to destination
ADC.B     Add carry to destination

Syntax     ADC    dst  or  ADC.W  dst
            ADC.B  dst

Operation  dst   +   C  -->  dst

Emulation  ADDC  #0,dst
            ADDC.B  #0,dst

Description The carry bit (C) is added to the destination operand. The previous contents of the destination are lost.

Status Bits  N:  Set if result is negative, reset if positive
            Z:  Set if result is zero, reset otherwise
            C:  Set if dst was incremented from 0FFFFh to 0000, reset otherwise
                 Set if dst was incremented from 0FFh to 00, reset otherwise
            V:  Set if an arithmetic overflow occurs, otherwise reset

Mode Bits   OSCOFF, CPUOFF, and GIE are not affected.

Example    The 16-bit counter pointed to by R13 is added to a 32-bit counter pointed to by R12.
            ADD    @R13,0(R12) ; Add LSDs
            ADC    2(R12)       ; Add carry to MSD

Example    The 8-bit counter pointed to by R13 is added to a 16-bit counter pointed to by R12.
            ADD.B   @R13,0(R12) ; Add LSDs
            ADC.B   1(R12)      ; Add carry to MSD
**Instruction Set**

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ADD.W</strong></td>
<td>Add source to destination</td>
</tr>
<tr>
<td><strong>ADD.B</strong></td>
<td>Add source to destination</td>
</tr>
</tbody>
</table>

**Syntax**

`ADD src,dst` or `ADD.W src,dst`

**ADD.B**

`src,dst`

**Operation**

`src + dst --> dst`

**Description**

The source operand is added to the destination operand. The source operand is not affected. The previous contents of the destination are lost.

**Status Bits**

- **N**: Set if result is negative, reset if positive
- **Z**: Set if result is zero, reset otherwise
- **C**: Set if there is a carry from the result, cleared if not
- **V**: Set if an arithmetic overflow occurs, otherwise reset

**Mode Bits**

- **OSCOFF**, **CPUOFF**, and **GIE** are not affected.

**Example**

R5 is increased by 10. The jump to TONI is performed on a carry.

```
ADD #10,R5
JC TONI ; Carry occurred
...... ; No carry
```

**Example**

R5 is increased by 10. The jump to TONI is performed on a carry.

```
ADD.B #10,R5 ; Add 10 to Lowbyte of R5
JC TONI ; Carry occurred, if (R5) ≥ 246 [0Ah+0F6h]
...... ; No carry
```
### ADDC[.W]
Add source and carry to destination

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADDC src,dst</td>
<td>src + dst + C → dst</td>
<td>The source operand and the carry bit (C) are added to the destination operand. The source operand is not affected. The previous contents of the destination are lost.</td>
</tr>
<tr>
<td>ADDC.W src,dst</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ADDC.B src,dst</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Status Bits
- **N**: Set if result is negative, reset if positive
- **Z**: Set if result is zero, reset otherwise
- **C**: Set if there is a carry from the MSB of the result, reset otherwise
- **V**: Set if an arithmetic overflow occurs, otherwise reset

### Mode Bits
OSCOFF, CPUOFF, and GIE are not affected.

### Example
The 32-bit counter pointed to by R13 is added to a 32-bit counter, eleven words (20/2 + 2/2) above the pointer in R13.

```
ADD @R13+,20(R13) ; ADD LSDs with no carry in
ADDC @R13+,20(R13) ; ADD MSDs with carry
... ; resulting from the LSDs
```

### Example
The 24-bit counter pointed to by R13 is added to a 24-bit counter, eleven words above the pointer in R13.

```
ADD.B @R13+,10(R13) ; ADD LSDs with no carry in
ADDC.B @R13+,10(R13) ; ADD medium Bits with carry
ADDC.B @R13+,10(R13) ; ADD MSDs with carry
... ; resulting from the LSDs
```
**Instruction Set**

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AND.[W]</strong></td>
<td>Source AND destination</td>
</tr>
<tr>
<td><strong>AND.B</strong></td>
<td>Source AND destination</td>
</tr>
</tbody>
</table>

**Syntax**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND src,dst or AND.W src,dst</td>
<td></td>
</tr>
<tr>
<td>AND.B src,dst</td>
<td></td>
</tr>
</tbody>
</table>

**Operation**

src .AND. dst -> dst

**Description**

The source operand and the destination operand are logically ANDed. The result is placed into the destination.

**Status Bits**

- **N**: Set if result MSB is set, reset if not set
- **Z**: Set if result is zero, reset otherwise
- **C**: Set if result is not zero, reset otherwise ( = .NOT. Zero)
- **V**: Reset

**Mode Bits**

OSCOFF, CPUOFF, and GIE are not affected.

**Example**

The bits set in R5 are used as a mask (#0AA55h) for the word addressed by TOM. If the result is zero, a branch is taken to label TONI.

```assembly
MOV #0AA55h,R5 ; Load mask into register R5
AND R5,TOM ; mask word addressed by TOM with R5
JZ TONI ; Result is not zero
...... ; or
```

**Example**

The bits of mask #0A5h are logically ANDed with the low byte TOM. If the result is zero, a branch is taken to label TONI.

```assembly
AND.B #0A5h,TOM ; mask Lowbyte TOM with 0A5h
JZ TONI ; Result is not zero
```
Instruction Set

### BIC.W
- **Clear bits in destination**

### BIC.B
- **Clear bits in destination**

#### Syntax
- `BIC src,dst` or `BIC.W src,dst`
- `BIC.B src,dst`

#### Operation
- `.NOT.src .AND. dst -> dst`

#### Description
The inverted source operand and the destination operand are logically ANDed. The result is placed into the destination. The source operand is not affected.

#### Status Bits
- Status bits are not affected.

#### Mode Bits
- `OSCOFF`, `CPUOFF`, and `GIE` are not affected.

#### Example
- **The six MSBs of the RAM word LEO are cleared.**
  ```
  BIC #0FC00h,LEO ; Clear 6 MSBs in MEM(LEO)
  ```

#### Example
- **The five MSBs of the RAM byte LEO are cleared.**
  ```
  BIC.B #0F8h,LEO ; Clear 5 MSBs in Ram location LEO
  ```
BIS[.W] Set bits in destination
BIS.B Set bits in destination

Syntax
BIS src,dst or BIS.W src,dst
BIS.B src,dst

Operation
src .OR. dst → dst

Description
The source operand and the destination operand are logically ORed. The result is placed into the destination. The source operand is not affected.

Status Bits
Status bits are not affected.

Mode Bits
OSCOFF, CPUOFF, and GIE are not affected.

Example
The six LSBs of the RAM word TOM are set.
BIS #003Fh,TOM; set the six LSBs in RAM location TOM

Example
The three MSBs of RAM byte TOM are set.
BIS.B #0E0h,TOM ; set the 3 MSBs in RAM location TOM
### BIT [.W]
Test bits in destination.

### BIT .B
Test bits in destination.

#### Syntax
BIT src, dst or BIT .W src, dst

#### Operation
src .AND. dst

#### Description
The source and destination operands are logically ANDed. The result affects only the status bits. The source and destination operands are not affected.

#### Status Bits
- N: Set if MSB of result is set, reset otherwise
- Z: Set if result is zero, reset otherwise
- C: Set if result is not zero, reset otherwise (.NOT. Zero)
- V: Reset

#### Mode Bits
OSCOFF, CPUOFF, and GIE are not affected.

#### Example
If bit 9 of R8 is set, a branch is taken to label TOM.

```assembly
BIT #0200h,R8 ; bit 9 of R8 set?
JNZ TOM ; Yes, branch to TOM
... ; No, proceed
```

#### Example
If bit 3 of R8 is set, a branch is taken to label TOM.

```assembly
BIT .B #8,R8
JC TOM
```

#### Example
A serial communication receive bit (RCV) is tested. Because the carry bit is equal to the state of the tested bit while using the BIT instruction to test a single bit, the carry bit is used by the subsequent instruction; the read information is shifted into register RECBUF.

```assembly
; Serial communication with LSB is shifted first:
BIT .B #RCV,RCCTL ; Bit info into carry
RRC RECBUF ; Carry -> MSB of RECBUF
...... ; repeat previous two instructions
...... ; 8 times
; MSB LSB

; Serial communication with MSB shifted first:
BIT .B #RCV,RCCTL ; Bit info into carry
RLC.B RECBUF ; Carry -> LSB of RECBUF
...... ; repeat previous two instructions
...... ; 8 times
; MSB LSB
```

---

*RISC 16–Bit CPU* 3-27
**Instruction Set**

* **BR, BRANCH**  
  Branch to ........... destination

**Syntax**  
BR dst

**Operation**  
dst \(\rightarrow\) PC

**Emulation**  
MOV dst,PC

**Description**  
An unconditional branch is taken to an address anywhere in the 64K address space. All source addressing modes can be used. The branch instruction is a word instruction.

**Status Bits**  
Status bits are not affected.

**Example**  
Examples for all addressing modes are given.

BR #EXEC ; Branch to label EXEC or direct branch (e.g. #0A4h)  
; Core instruction MOV @PC+,PC

BR EXEC ; Branch to the address contained in EXEC  
; Core instruction MOV X(PC),PC  
; Indirect address

BR &EXEC ; Branch to the address contained in absolute  
; address EXEC  
; Core instruction MOV X(0),PC  
; Indirect address

BR R5 ; Branch to the address contained in R5  
; Core instruction MOV R5,PC  
; Indirect R5

BR @R5 ; Branch to the address contained in the word  
; pointed to by R5.  
; Core instruction MOV @R5,PC  
; Indirect, indirect R5

BR @R5+ ; Branch to the address contained in the word pointed  
; to by R5 and increment pointer in R5 afterwards.  
; The next time—S/W flow uses R5 pointer—it can  
; alter program execution due to access to  
; next address in a table pointed to by R5  
; Core instruction MOV @R5,PC  
; Indirect, indirect R5 with autoincrement

BR X(R5) ; Branch to the address contained in the address  
; pointed to by R5 + X (e.g. table with address  
; starting at X). X can be an address or a label  
; Core instruction MOV X(R5),PC  
; Indirect, indirect R5 + X
CALL

Subroutine

Syntax

CALL dst

Operation

dst -> tmp   dst is evaluated and stored
SP - 2 -> SP
PC -> @SP   PC updated to TOS
tmp -> PC    dst saved to PC

Description

A subroutine call is made to an address anywhere in the 64K address space. All addressing modes can be used. The return address (the address of the following instruction) is stored on the stack. The call instruction is a word instruction.

Status Bits

Status bits are not affected.

Example

Examples for all addressing modes are given.

CALL #EXEC ; Call on label EXEC or immediate address (e.g. #0A4h)
; SP-2 → SP, PC+2 → @SP, @PC+ → PC

CALL EXEC ; Call on the address contained in EXEC
; SP-2 → SP, PC+2 → @SP, X(PC) → PC
; Indirect address

CALL &EXEC ; Call on the address contained in absolute address
; EXEC
; SP-2 → SP, PC+2 → @SP, X(0) → PC
; Indirect address

CALL R5 ; Call on the address contained in R5
; SP-2 → SP, PC+2 → @SP, R5 → PC
; Indirect R5

CALL @R5 ; Call on the address contained in the word
; pointed to by R5
; SP-2 → SP, PC+2 → @SP, @R5 → PC
; Indirect, indirect R5

CALL @R5+ ; Call on the address contained in the word
; pointed to by R5 and increment pointer in R5.
; The next time—S/W flow uses R5 pointer—
; it can alter the program execution due to
; access to next address in a table pointed to by R5
; SP-2 → SP, PC+2 → @SP, @R5 → PC
; Indirect, indirect R5 with autoincrement

CALL X(R5) ; Call on the address contained in the address pointed
; to by R5 + X (e.g. table with address starting at X)
; X can be an address or a label
; SP-2 → SP, PC+2 → @SP, X(R5) → PC
; Indirect, indirect R5 + X
### Instruction Set

<table>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLR.W</td>
<td>Clear destination</td>
</tr>
<tr>
<td>CLR.B</td>
<td>Clear destination</td>
</tr>
</tbody>
</table>

**Syntax**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLR dst or CLR.W dst</td>
<td>0 -&gt; dst</td>
</tr>
<tr>
<td>CLR.B dst</td>
<td>0 -&gt; dst</td>
</tr>
</tbody>
</table>

**Emulation**

<table>
<thead>
<tr>
<th>Emulation</th>
<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV #0,dst</td>
<td>MOV.B #0,dst</td>
</tr>
</tbody>
</table>

**Description**

The destination operand is cleared.

**Status Bits**

Status bits are not affected.

**Example**

RAM word TONI is cleared.

```assembly
CLR TONI ; 0 -> TONI
```

Register R5 is cleared.

```assembly
CLR R5
```

RAM byte TONI is cleared.

```assembly
CLR.B TONI ; 0 -> TONI
```
* **CLRC**

Clear carry bit

**Syntax**

CLRC

**Operation**

0 -> C

**Emulation**

BIC #1,SR

**Description**

The carry bit (C) is cleared. The clear carry instruction is a word instruction.

**Status Bits**

N: Not affected
Z: Not affected
C: Cleared
V: Not affected

**Mode Bits**

OSCOFF, CPUOFF, and GIE are not affected.

**Example**

The 16-bit decimal counter pointed to by R13 is added to a 32-bit counter pointed to by R12.

```
CLRC ; C=0: defines start
DADD @R13,0(R12) ; add 16-bit counter to low word of 32-bit counter
DADC 2(R12) ; add carry to high word of 32-bit counter
```
* **CLRN**  
Clear negative bit

**Syntax**

CLRN

**Operation**

0 → N  
or  
(.NOT.src .AND. dst → dst)

**Emulation**

BIC #4,SR

**Description**

The constant 04h is inverted (0FFFBh) and is logically ANDed with the destination operand. The result is placed into the destination. The clear negative bit instruction is a word instruction.

**Status Bits**

N: Reset to 0  
Z: Not affected  
C: Not affected  
V: Not affected

**Mode Bits**

OSCOFF, CPUOFF, and GIE are not affected.

**Example**

The Negative bit in the status register is cleared. This avoids special treatment with negative numbers of the subroutine called.

```
CLRN
CALL SUBR
......
......
SUBR JN SUBRET ; If input is negative: do nothing and return
......
......
SUBRET RET
```
* CLRZ  
Clear zero bit

**Syntax**  
CLRZ

**Operation**  
0 → Z  
or  
(.NOT.src .AND. dst → dst)

**Emulation**  
BIC #2,SR

**Description**  
The constant 02h is inverted (0FFFDh) and logically ANDed with the destination operand. The result is placed into the destination. The clear zero bit instruction is a word instruction.

**Status Bits**  
N: Not affected  
Z: Reset to 0  
C: Not affected  
V: Not affected

**Mode Bits**  
OSCOFF, CPUOFF, and GIE are not affected.

**Example**  
The zero bit in the status register is cleared.  
CLRZ
Instruction Set

CMP[W]  Compare source and destination
CMP.B   Compare source and destination

Syntax

CMP src,dst or CMP.W src,dst
CMP.B src,dst

Operation
dst + .NOT.src + 1
or
(dst – src)

Description
The source operand is subtracted from the destination operand. This is accomplished by adding the 1s complement of the source operand plus 1. The two operands are not affected and the result is not stored; only the status bits are affected.

Status Bits
N: Set if result is negative, reset if positive (src >= dst)
Z: Set if result is zero, reset otherwise (src = dst)
C: Set if there is a carry from the MSB of the result, reset otherwise
V: Set if an arithmetic overflow occurs, otherwise reset

Mode Bits
OSCOFF, CPUOFF, and GIE are not affected.

Example
R5 and R6 are compared. If they are equal, the program continues at the label EQUAL.

CMP R5,R6  ; R5 = R6?
JEQ EQUAL  ; YES, JUMP

Example
Two RAM blocks are compared. If they are not equal, the program branches to the label ERROR.

MOV #NUM,R5  ; number of words to be compared
MOV #BLOCK1,R6  ; BLOCK1 start address in R6
MOV #BLOCK2,R7  ; BLOCK2 start address in R7
L$1 CMP @R6+,0(R7)  ; Are Words equal? R6 increments
JNZ ERROR  ; No, branch to ERROR
INCD R7  ; Increment R7 pointer
DEC R5  ; Are all words compared?
JNZ L$1  ; No, another compare

Example
The RAM bytes addressed by EDE and TONI are compared. If they are equal, the program continues at the label EQUAL.

CMP.B EDE,TONI  ; MEM(EDE) = MEM(TONI)?
JEQ EQUAL  ; YES, JUMP
**DADC[.W]**  Add carry decimally to destination
**DADC.B**  Add carry decimally to destination

**Syntax**
- DADC dst    or    DADC.W src,dst
- DADC.B dst

**Operation**
- dst + C -> dst (decimally)

**Emulation**
- DADD #0,dst
- DADD.B #0,dst

**Description**
The carry bit (C) is added decimally to the destination.

**Status Bits**
- N: Set if MSB is 1
- Z: Set if dst is 0, reset otherwise
- C: Set if destination increments from 9999 to 0000, reset otherwise
  - Set if destination increments from 99 to 00, reset otherwise
- V: Undefined

**Mode Bits**
OSCOFF, CPUOFF, and GIE are not affected.

**Example**
The four-digit decimal number contained in R5 is added to an eight-digit decimal number pointed to by R8.
```
CLRC ; Reset carry
DADD R5,0(R8) ; Add LSDs + C
DADC 2(R8) ; Add carry to MSD
```

**Example**
The two-digit decimal number contained in R5 is added to a four-digit decimal number pointed to by R8.
```
CLRC ; Reset carry
DADD.B R5,0(R8) ; Add LSDs + C
DADC 1(R8) ; Add carry to MSDs
### Instruction Set

**DADD[.W]**  
Source and carry added decimally to destination  

**DADD.B**  
Source and carry added decimally to destination  

**Syntax**  

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DADD</td>
<td>src, dst</td>
</tr>
<tr>
<td>DADD.W</td>
<td>src, dst</td>
</tr>
<tr>
<td>DADD.B</td>
<td>src, dst</td>
</tr>
</tbody>
</table>

**Operation**  
src + dst + C -> dst (decimally)

**Description**  
The source operand and the destination operand are treated as four binary coded decimals (BCD) with positive signs. The source operand and the carry bit (C) are added decimally to the destination operand. The source operand is not affected. The previous contents of the destination are lost. The result is not defined for non-BCD numbers.

**Status Bits**  

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Set if the MSB is 1, reset otherwise</td>
</tr>
<tr>
<td>Z</td>
<td>Set if result is zero, reset otherwise</td>
</tr>
</tbody>
</table>
| C   | Set if the result is greater than 9999  
|     | Set if the result is greater than 99  
| V   | Undefined                     |

**Mode Bits**  
OSCOFF, CPUOFF, and GIE are not affected.

**Example**  
The eight-digit BCD number contained in R5 and R6 is added decimally to an eight-digit BCD number contained in R3 and R4 (R6 and R4 contain the MSDs).

```
CLRC ; clear carry
DADD R5,R3 ; add LSDs
DADD R6,R4 ; add MSDs with carry
JC OVERFLOW ; If carry occurs go to error handling routine
```

**Example**  
The two-digit decimal counter in the RAM byte CNT is incremented by one.

```
CLRC ; clear carry
DADD.B #1,CNT ; increment decimal counter
```

or

```
SETC
DADD.B #0,CNT ; ≡ DADC.B CNT
```
* DEC[W]
  Decrement destination
* DEC.B
  Decrement destination

**Syntax**
DEC dst or DEC.W dst
DEC.B dst

**Operation**
dst – 1 -> dst

**Emulation**
SUB #1,dst
SUB.B #1,dst

**Description**
The destination operand is decremented by one. The original contents are lost.

**Status Bits**
N: Set if result is negative, reset if positive
Z: Set if dst contained 1, reset otherwise
C: Reset if dst contained 0, set otherwise
V: Set if an arithmetic overflow occurs, otherwise reset.
  Set if initial value of destination was 08000h, otherwise reset.
  Set if initial value of destination was 080h, otherwise reset.

**Mode Bits**
OSCOFF, CPUOFF, and GIE are not affected.

**Example**
R10 is decremented by 1

DEC R10 ; Decrement R10
; Move a block of 255 bytes from memory location starting with EDE to memory location starting with TONI. Tables should not overlap: start of destination address TONI must not be within the range EDE to EDE+0FEh
; to EDE+0FEh
;
MOV #EDE,R6
MOV #255,R10
L$1
MOV.B @R6+;TONI–EDE–1(R6)
DEC R10
JNZ L$1

; Do not transfer tables using the routine above with the overlap shown in Figure 3–12.

**Figure 3–12. Decrement Overlap**

<tr>
<td></td>
<td>Set if initial value of destination was 081 or 080h, otherwise reset.</td>
</tr>
</tbody>
</table>

#### Mode Bits

OSCOFF, CPUOFF, and GIE are not affected.

#### Example

R10 is decremented by 2.

```assembly
DECD R10 ; Decrement R10 by two
```

Move a block of 255 words from memory location starting with EDE to memory location starting with TONI.

```assembly
MOV #EDE,R6
MOV #510,R10
L$1 MOV @R6+,TONI–EDE–2(R6)
DECD R10
JNZ L$1
```

In the second example, the memory at location LEO is decremented by two.

```assembly
DECD.B LEO ; Decrement MEM(LEO)
```

Decrement status byte STATUS by two.

```assembly
DECD.B STATUS
```
* DINT

Disable (general) interrupts

Syntax

DINT

Operation

0 → GIE
or
(0FFF7h .AND. SR → SR / .NOT.src .AND. dst → dst)

Emulation

BIC #8,SR

Description

All interrupts are disabled.
The constant 08h is inverted and logically ANDed with the status register (SR).
The result is placed into the SR.

Status Bits

Status bits are not affected.

Mode Bits

GIE is reset. OSCOFF and CPUOFF are not affected.

Example

The general interrupt enable (GIE) bit in the status register is cleared to allow
a nondisrupted move of a 32-bit counter. This ensures that the counter is not
modified during the move by any interrupt.

DINT ; All interrupt events using the GIE bit are disabled
NOP
MOV COUNTHI,R5 ; Copy counter
MOV COUNTLO,R6
EINT ; All interrupt events using the GIE bit are enabled

Note: Disable Interrupt

If any code sequence needs to be protected from interruption, the DINT
should be executed at least one instruction before the beginning of the
uninterruptible sequence, or should be followed by a NOP instruction.
* EINT

Enable (general) interrupts

Syntax

EINT

Operation

1 → GIE
or
(0008h .OR. SR → SR / .src .OR. dst → dst)

Emulation

BIS #8,SR

Description

All interrupts are enabled. The constant #08h and the status register SR are logically ORed. The result is placed into the SR.

Status Bits

Status bits are not affected.

Mode Bits

GIE is set. OSCOFF and CPUOFF are not affected.

Example

The general interrupt enable (GIE) bit in the status register is set.

; Interrupt routine of ports P1.2 to P1.7
; P1IN is the address of the register where all port bits are read. P1IFG is the address of
; the register where all interrupt events are latched.

; PUSH.B &P1IN
BIC.B @SP,&P1IFG ; Reset only accepted flags
EINT ; Preset port 0 interrupt flags stored on stack
; other interrupts are allowed
BIT #Mask,@SP
JEQ MaskOK ; Flags are present identically to mask: jump

......
MaskOK
BIC #Mask,@SP

......
INCD SP ; Housekeeping: inverse to PUSH instruction
; at the start of interrupt subroutine. Corrects
; the stack pointer.
RETI

Note: Enable Interrupt

The instruction following the enable interrupt instruction (EINT) is always executed, even if an interrupt service request is pending when the interrupts are enable.
* INC.W
  Increment destination
* INC.B
  Increment destination

Syntax

- INC dst or INC.W dst
- INC.B dst

Operation
dst + 1 -> dst

Emulation
ADD #1, dst

Description
The destination operand is incremented by one. The original contents are lost.

Status Bits

- N: Set if result is negative, reset if positive
- Z: Set if dst contained 0FFFFh, reset otherwise
  Set if dst contained 0FFh, reset otherwise
- C: Set if dst contained 0FFFFh, reset otherwise
  Set if dst contained 0FFh, reset otherwise
- V: Set if dst contained 07FFFh, reset otherwise
  Set if dst contained 07Fh, reset otherwise

Mode Bits
OSCOFF, CPUOFF, and GIE are not affected.

Example
The status byte, STATUS, of a process is incremented. When it is equal to 11, a branch to OVFL is taken.

```
INC.B STATUS
CMP.B #11, STATUS
JEQ OVFL
```
### INCD[.W]
Double-increment destination

### INCD.B
Double-increment destination

#### Syntax
- **INCD dst** or **INCD.W dst**
- **INCD.B dst**

#### Operation
- dst + 2 → dst

#### Emulation
- **ADD #2,dst**
- **ADD.B #2,dst**

#### Example
The destination operand is incremented by two. The original contents are lost.

#### Status Bits
- **N**: Set if result is negative, reset if positive
- **Z**: Set if dst contained 0FFFEh, reset otherwise
  - Set if dst contained 0FEh, reset otherwise
- **C**: Set if dst contained 0FFFEh or 0FFFFh, reset otherwise
  - Set if dst contained 0FEh or 0FFh, reset otherwise
- **V**: Set if dst contained 07FFEh or 07FFFh, reset otherwise
  - Set if dst contained 07Eh or 07Fh, reset otherwise

#### Mode Bits
OSCOFF, CPUOFF, and GIE are not affected.

#### Example
The item on the top of the stack (TOS) is removed without using a register.

```
......
PUSH R5 ; R5 is the result of a calculation, which is stored
        ; in the system stack
INCD SP ; Remove TOS by double-increment from stack
        ; Do not use INCD.B, SP is a word-aligned
        ; register
RET
```

#### Example
The byte on the top of the stack is incremented by two.

```
INCD.B 0(SP) ; Byte on TOS is increment by two
```
**Instruction Set**

* **INV.W**
  Invert destination

* **INV.B**
  Invert destination

**Syntax**

```
INV dst
INV.B dst
```

**Operation**

```
.NOT. dst -> dst
```

**Emulation**

```
XOR #0FFFFh,dst
XOR.B #0FFh,dst
```

**Description**

The destination operand is inverted. The original contents are lost.

**Status Bits**

- **N**: Set if result is negative, reset if positive
- **Z**: Set if dst contained 0FFFFh, reset otherwise
  - Set if dst contained 0FFh, reset otherwise
- **C**: Set if result is not zero, reset otherwise ( = .NOT. Zero)
  - Set if result is not zero, reset otherwise ( = .NOT. Zero)
- **V**: Set if initial destination operand was negative, otherwise reset

**Mode Bits**

OSCOFF, CPUOFF, and GIE are not affected.

**Example**

Content of R5 is negated (twos complement).

```
MOV #00AEh,R5 ; R5 = 000AEh
INV R5 ; Invert R5, R5 = 0FF51h
INC R5 ; R5 is now negated, R5 = 0FF52h
```

Content of memory byte LEO is negated.

```
MOV.B #0AEh,LEO ; MEM(LEO) = 0AEh
INV.B LEO ; Invert LEO, MEM(LEO) = 051h
INC.B LEO ; MEM(LEO) is negated, MEM(LEO) = 052h
```
**Instruction Set**

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JC</td>
<td>Jump if carry set</td>
</tr>
<tr>
<td>JHS</td>
<td>Jump if higher or same</td>
</tr>
</tbody>
</table>

**Syntax**

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>JC</td>
<td>JC label</td>
</tr>
<tr>
<td>JHS</td>
<td>JHS label</td>
</tr>
</tbody>
</table>

**Operation**

- If C = 1: PC + 2 × offset → PC
- If C = 0: execute following instruction

**Description**

The status register carry bit (C) is tested. If it is set, the 10-bit signed offset contained in the instruction LSBs is added to the program counter. If C is reset, the next instruction following the jump is executed. JC (jump if carry/higher or same) is used for the comparison of unsigned numbers (0 to 65536).

**Status Bits**

Status bits are not affected.

**Example**

The P1IN.1 signal is used to define or control the program flow.

```
BIT #01h,&P1IN ; State of signal -> Carry
JC PROGA ; If carry=1 then execute program routine A
...... ; Carry=0, execute program here
```

**Example**

R5 is compared to 15. If the content is higher or the same, branch to LABEL.

```
CMP #15,R5
JHS LABEL ; Jump is taken if R5 ≥ 15
...... ; Continue here if R5 < 15
```
**JEQ, JZ**  
Jump if equal, jump if zero

**Syntax**  
JEQ  label,  JZ  label

**Operation**  
If $Z = 1$:  $PC + 2 \times \text{offset} \rightarrow PC$
If $Z = 0$: execute following instruction

**Description**  
The status register zero bit ($Z$) is tested. If it is set, the 10-bit signed offset contained in the instruction LSBs is added to the program counter. If $Z$ is not set, the instruction following the jump is executed.

**Status Bits**  
Status bits are not affected.

**Example**  
Jump to address TONI if R7 contains zero.

```
TST  R7  ; Test R7
JZ  TONI  ; if zero: JUMP
```

**Example**  
Jump to address LEO if R6 is equal to the table contents.

```
CMP  R6,Table(R5)  ; Compare content of R6 with content of MEM (table address + content of R5)
JEQ  LEO  ; Jump if both data are equal
.......  ; No, data are not equal, continue here
```

**Example**  
Branch to LABEL if R5 is 0.

```
TST  R5
JZ  LABEL
.......  
```
**Instruction Set**

**JGE**  
Jump if greater or equal

**Syntax**  
JGE label

**Operation**  
If (N .XOR. V) = 0 then jump to label: PC + 2 × offset → PC  
If (N .XOR. V) = 1 then execute the following instruction

**Description**  
The status register negative bit (N) and overflow bit (V) are tested. If both N and V are set or reset, the 10-bit signed offset contained in the instruction LSBs is added to the program counter. If only one is set, the instruction following the jump is executed.

This allows comparison of signed integers.

**Status Bits**  
Status bits are not affected.

**Example**  
When the content of R6 is greater or equal to the memory pointed to by R7, the program continues at label EDE.

```
CMP @R7,R6 ; R6 ≥ (R7)?, compare on signed numbers
JGE EDE ; Yes, R6 ≥ (R7)
...... ; No, proceed
......
......
```
<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JL</td>
<td>Jump if less</td>
</tr>
</tbody>
</table>

**Syntax**

| JL | label |

**Operation**

- If \((N \text{ XOR } V) = 1\) then jump to label: \(PC + 2 \times \text{offset} \rightarrow PC\)
- If \((N \text{ XOR } V) = 0\) then execute following instruction

**Description**

The status register negative bit \((N)\) and overflow bit \((V)\) are tested. If only one is set, the 10-bit signed offset contained in the instruction LSBs is added to the program counter. If both \(N\) and \(V\) are set or reset, the instruction following the jump is executed.

This allows comparison of signed integers.

**Status Bits**

Status bits are not affected.

**Example**

When the content of \(R6\) is less than the memory pointed to by \(R7\), the program continues at label EDE.

```
CMP @R7,R6 ; R6 < (R7)?, compare on signed numbers
JL EDE ; Yes, R6 < (R7)
...... ; No, proceed
......
......
```
<table>

<tr>
<td><strong>Description</strong></td>
</tr>
<tr>
<td><strong>Status Bits</strong></td>
</tr>
<tr>
<td><strong>Hint:</strong></td>
</tr>
</tbody>
</table>
**JN**

Jump if negative

**Syntax**

JN    label

**Operation**

if $N = 1$: $PC + 2 \times \text{offset} \rightarrow PC$
if $N = 0$: execute following instruction

**Description**

The negative bit ($N$) of the status register is tested. If it is set, the 10-bit signed offset contained in the instruction LSBs is added to the program counter. If $N$ is reset, the next instruction following the jump is executed.

**Status Bits**

Status bits are not affected.

**Example**

The result of a computation in R5 is to be subtracted from COUNT. If the result is negative, COUNT is to be cleared and the program continues execution in another path.

```
SUB    R5,COUNT  ; COUNT – R5 → COUNT
JN     L$1      ; If negative continue with COUNT=0 at PC=L$1
...... ; Continue with COUNT≥0
......
......
......
L$1    CLR       COUNT
......
......
......
```
### Instruction Set

**JNC**
Jump if carry not set

**JLO**
Jump if lower

**Syntax**

- JNC label
- JLO label

**Operation**

- if $C = 0$: $PC + 2 \times \text{offset} \rightarrow PC$
- if $C = 1$: execute following instruction

**Description**
The status register carry bit ($C$) is tested. If it is reset, the 10-bit signed offset contained in the instruction LSBs is added to the program counter. If $C$ is set, the next instruction following the jump is executed. **JNC** (jump if no carry/lower) is used for the comparison of unsigned numbers (0 to 65536).

**Status Bits**
Status bits are not affected.

**Example**
The result in R6 is added in BUFFER. If an overflow occurs, an error handling routine at address ERROR is used.

```
ADD R6, BUFFER ; BUFFER + R6 -> BUFFER
JNC CONT ; No carry, jump to CONT
```

```
ERROR ...... ; Error handler start
......
......
```

```
CONT ...... ; Continue with normal program flow
......
```

**Example**
Branch to STL2 if byte STATUS contains 1 or 0.

```
CMP.B #2, STATUS
JLO STL2 ; STATUS < 2
...... ; STATUS \geq 2, continue here
```
JNE  Jump if not equal
JNZ  Jump if not zero

Syntax  
JNE  label
JNZ  label

Operation  
If $Z = 0$: $PC + 2 \times \text{offset} \rightarrow PC$
If $Z = 1$: execute following instruction

Description  
The status register zero bit ($Z$) is tested. If it is reset, the 10-bit signed offset contained in the instruction LSBs is added to the program counter. If $Z$ is set, the next instruction following the jump is executed.

Status Bits  
Status bits are not affected.

Example  
Jump to address TONI if R7 and R8 have different contents.

```
CMP R7,R8 ; COMPARE R7 WITH R8
JNE TONI   ; if different: jump
......      ; if equal, continue
```
### Instruction Set

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV.W</td>
<td>Move source to destination</td>
</tr>
<tr>
<td>MOV.B</td>
<td>Move source to destination</td>
</tr>
</tbody>
</table>

**Syntax**

- MOV src,dst or MOV.W src,dst
- MOV.B src,dst

**Operation**

src -> dst

**Description**

The source operand is moved to the destination. The source operand is not affected. The previous contents of the destination are lost.

**Status Bits**

Status bits are not affected.

**Mode Bits**

OSCOFF, CPUOFF, and GIE are not affected.

**Example**

The contents of table EDE (word data) are copied to table TOM. The length of the tables must be 020h locations.

```
MOV #EDE,R10 ; Prepare pointer
MOV #020h,R9 ; Prepare counter

Loop
    MOV @R10+,TOM–EDE–2(R10) ; Use pointer in R10 for both tables
    DEC R9 ; Decrement counter
    JNZ Loop ; Counter ≠ 0, continue copying

...... ; Copying completed
```

**Example**

The contents of table EDE (byte data) are copied to table TOM. The length of the tables should be 020h locations.

```
MOV #EDE,R10 ; Prepare pointer
MOV #020h,R9 ; Prepare counter

Loop
    MOV.B @R10+,TOM–EDE–1(R10) ; Use pointer in R10 for both tables
    DEC R9 ; Decrement counter
    JNZ Loop ; Counter ≠ 0, continue copying

...... ; Copying completed
```
* NOP  

No operation

Syntax  
NOP

Operation  
None

Emulation  
MOV #0, R3

Description  
No operation is performed. The instruction may be used for the elimination of instructions during the software check or for defined waiting times.

Status Bits  
Status bits are not affected.

The NOP instruction is mainly used for two purposes:

- To fill one, two, or three memory words
- To adjust software timing

**Note: Emulating No-Operation Instruction**

Other instructions can emulate the NOP function while providing different numbers of instruction cycles and code words. Some examples are:

Examples:

- MOV #0,R3 ; 1 cycle, 1 word
- MOV 0(R4),0(R4) ; 6 cycles, 3 words
- MOV @R4,0(R4) ; 5 cycles, 2 words
- BIC #0,EDE(R4) ; 4 cycles, 2 words
- JMP $+2 ; 2 cycles, 1 word
- BIC #0,R5 ; 1 cycle, 1 word

However, care should be taken when using these examples to prevent unintended results. For example, if MOV 0(R4), 0(R4) is used and the value in R4 is 120h, then a security violation will occur with the watchdog timer (address 120h) because the security key was not used.
**Instruction Set**

* **POP[W]**  
  Pop word from stack to destination

* **POP.B**  
  Pop byte from stack to destination

**Syntax**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>POP</td>
<td>dst</td>
</tr>
<tr>
<td>POP.B</td>
<td>dst</td>
</tr>
</tbody>
</table>

**Operation**

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@SP -&gt; temp</td>
<td>The stack location pointed to by the stack pointer (TOS) is moved to the destination. The stack pointer is incremented by two afterwards.</td>
</tr>
<tr>
<td>SP + 2 -&gt; SP</td>
<td>temp -&gt; dst</td>
</tr>
</tbody>
</table>

**Emulation**

<table>
<thead>
<tr>
<th>Emulation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV @SP+,dst</td>
<td>or MOV.W @SP+,dst</td>
</tr>
<tr>
<td>MOV.B @SP+,dst</td>
<td></td>
</tr>
</tbody>
</table>

**Description**

The stack location pointed to by the stack pointer (TOS) is moved to the destination. The stack pointer is incremented by two afterwards.

**Status Bits**

Status bits are not affected.

**Example**

The contents of R7 and the status register are restored from the stack.

```assembly
POP R7 ; Restore R7
POP SR ; Restore status register
```

The contents of RAM byte LEO is restored from the stack.

```assembly
POP.B LEO ; The low byte of the stack is moved to LEO.
```

The contents of R7 is restored from the stack.

```assembly
POP.B R7 ; The low byte of the stack is moved to R7, the high byte of R7 is 00h
```

The contents of the memory pointed to by R7 and the status register are restored from the stack.

```assembly
POP.B 0(R7) ; The low byte of the stack is moved to the byte which is pointed to by R7
            ; Example: R7 = 203h
            ; Mem(R7) = low byte of system stack
            ; Example: R7 = 20Ah
            ; Mem(R7) = low byte of system stack
POP SR ; Last word on stack moved to the SR
```

**Note:** The System Stack Pointer

The system stack pointer (SP) is always incremented by two, independent of the byte suffix.
<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PUSH[.W]</strong></td>
<td>Push word onto stack</td>
</tr>
<tr>
<td><strong>PUSH.B</strong></td>
<td>Push byte onto stack</td>
</tr>
</tbody>
</table>

**Syntax**

- `PUSH src` or `PUSH.W src`
- `PUSH.B src`

**Operation**

- `SP – 2 → SP`
- `src → @SP`

**Description**

The stack pointer is decremented by two, then the source operand is moved to the RAM word addressed by the stack pointer (TOS).

**Status Bits**

Status bits are not affected.

**Mode Bits**

OSCOFF, CPUOFF, and GIE are not affected.

**Example**

The contents of the status register and R8 are saved on the stack.

```
PUSH SR ; save status register
PUSH R8 ; save R8
```

**Example**

The contents of the peripheral TCDAT is saved on the stack.

```
PUSH.B &TCDAT ; save data from 8-bit peripheral module, ; address TCDAT, onto stack
```

**Note:** The System Stack Pointer

The system stack pointer (SP) is always decremented by two, independent of the byte suffix.
**RET**          Return from subroutine

**Syntax**        RET

**Operation**    @SP → PC
                 SP + 2 → SP

**Emulation**    MOV @SP+,PC

**Description**  The return address pushed onto the stack by a CALL instruction is moved to
                 the program counter. The program continues at the code address following the
                 subroutine call.

**Status Bits**  Status bits are not affected.
**RETI**

Return from interrupt

**Syntax**

RETI

**Operation**

- TOS → SR
- SP + 2 → SP
- TOS → PC
- SP + 2 → SP

**Description**

The status register is restored to the value at the beginning of the interrupt service routine by replacing the present SR contents with the TOS contents. The stack pointer (SP) is incremented by two.

The program counter is restored to the value at the beginning of interrupt service. This is the consecutive step after the interrupted program flow. Restoration is performed by replacing the present PC contents with the TOS memory contents. The stack pointer (SP) is incremented.

**Status Bits**

- N: restored from system stack
- Z: restored from system stack
- C: restored from system stack
- V: restored from system stack

**Mode Bits**

OSCOFF, CPUOFF, and GIE are restored from system stack.

**Example**

Figure 3–13 illustrates the main program interrupt.

---

*Figure 3–13. Main Program Interrupt*
Instruction Set

* RLA[W]  Rotate left arithmetically
* RLA.B  Rotate left arithmetically

Syntax

<table>
<thead>
<tr>
<th>Operation</th>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>C ← MSB ← MSB−1 .... LSB+1 ← LSB ← 0</td>
<td>RLA dst or RLA.W dst</td>
</tr>
<tr>
<td></td>
<td>RLA.B dst</td>
</tr>
</tbody>
</table>

Description

The destination operand is shifted left one position as shown in Figure 3–14. The MSB is shifted into the carry bit (C) and the LSB is filled with 0. The RLA instruction acts as a signed multiplication by 2.

An overflow occurs if dst ≥ 04000h and dst < 0C000h before operation is performed: the result has changed sign.

Figure 3–14. Destination Operand—Arithmetic Shift Left

An overflow occurs if dst ≥ 040h and dst < 0C0h before the operation is performed: the result has changed sign.

Status Bits

N: Set if result is negative, reset if positive
Z: Set if result is zero, reset otherwise
C: Loaded from the MSB
V: Set if an arithmetic overflow occurs:
    the initial value is 04000h ≤ dst < 0C000h; reset otherwise
    Set if an arithmetic overflow occurs:
    the initial value is 040h ≤ dst < 0C0h; reset otherwise

Mode Bits

OSCOFF, CPuOFF, and GIE are not affected.

Example

R7 is multiplied by 2.

RLA R7 ; Shift left R7 (× 2)

Example

The low byte of R7 is multiplied by 4.

RLA.B R7 ; Shift left low byte of R7 (× 2)
RLA.B R7 ; Shift left low byte of R7 (× 4)

Note: RLA Substitution

The assembler does not recognize the instruction:

RLA @R5+ nor RLA.B @R5+.

It must be substituted by:

ADD @R5+,-2(R5) or ADD.B @R5+,-1(R5).
* RLC[W]  
  Rotate left through carry

* RLC.B  
  Rotate left through carry

Syntax  
RLC dst or RLC.W dst
RLC.B dst

Operation  
C ← MSB ← MSB−1 .... LSB+1 ← LSB ← C

Emulation  
ADDC dst,dst

Description  
The destination operand is shifted left one position as shown in Figure 3–15. The carry bit (C) is shifted into the LSB and the MSB is shifted into the carry bit (C).

Figure 3–15. Destination Operand—Carry Left Shift

Status Bits  
N: Set if result is negative, reset if positive
Z: Set if result is zero, reset otherwise
C: Loaded from the MSB
V: Set if an arithmetic overflow occurs
  the initial value is 04000h ≤ dst < 0C000h; reset otherwise
  Set if an arithmetic overflow occurs:
  the initial value is 040h ≤ dst < 0C0h; reset otherwise

Mode Bits  
OSCOFF, CPUOFF, and GIE are not affected.

Example  
R5 is shifted left one position.
RLC R5 ; (R5 x 2) + C ← R5

Example  
The input P1IN.1 information is shifted into the LSB of R5.
BIT.B #2,&P1IN ; Information ← Carry
RLC R5 ; Carry=P0in.1 ← LSB of R5

Example  
The MEM(LEO) content is shifted left one position.
RLC.B LEO ; Mem(LEO) x 2 + C ← Mem(LEO)

Note: RLC and RLC.B Substitution
The assembler does not recognize the instruction:
RLC @R5+.
It must be substituted by:
ADDC @R5+,-2(R5).

RISC 16–Bit CPU  3-59
Instruction Set

**RRA[.W]**
Rotate right arithmetically

**RRA.B**
Rotate right arithmetically

**Syntax**
RRA dst or RRA.W dst
RRA.B dst

**Operation**
MSB → MSB, MSB → MSB–1, ... LSB+1 → LSB, LSB → C

**Description**
The destination operand is shifted right one position as shown in Figure 3–16. The MSB is shifted into the MSB, the MSB is shifted into the MSB–1, and the LSB+1 is shifted into the LSB.

**Figure 3–16. Destination Operand—Arithmetic Right Shift**

---

**Status Bits**
N: Set if result is negative, reset if positive
Z: Set if result is zero, reset otherwise
C: Loaded from the LSB
V: Reset

**Mode Bits**
OSCOFF, CPUOFF, and GIE are not affected.

**Example**
R5 is shifted right one position. The MSB retains the old value. It operates equal to an arithmetic division by 2.

```
RRA R5 ; R5/2 → R5
```

The value in R5 is multiplied by 0.75 (0.5 + 0.25).

```
PUSH R5 ; Hold R5 temporarily using stack
RRA R5 ; R5 × 0.5 → R5
ADD @SP+,R5 ; R5 × 0.5 + R5 = 1.5 × R5 → R5
RRA R5 ; (1.5 × R5) × 0.5 = 0.75 × R5 → R5
......
```

**Example**
The low byte of R5 is shifted right one position. The MSB retains the old value. It operates equal to an arithmetic division by 2.

```
RRA.B R5 ; R5/2 → R5: operation is on low byte only
; High byte of R5 is reset
PUSH.B R5 ; R5 × 0.5 → TOS
RRA.B @SP ; TOS × 0.5 = 0.5 × R5 × 0.5 = 0.25 × R5 → TOS
ADD.B @SP+,R5 ; R5 × 0.5 + R5 × 0.25 = 0.75 × R5 → R5
......
```
**RRC[.W]**  Rotate right through carry  
**RRC.B**  Rotate right through carry  

**Syntax**  
RRC dst or RRC.W dst  
RRC dst  

**Operation**  
C → MSB → MSB−1 .... LSB+1 → LSB → C  

**Description**  
The destination operand is shifted right one position as shown in Figure 3–17. The carry bit (C) is shifted into the MSB, the LSB is shifted into the carry bit (C).  

**Figure 3–17. Destination Operand—Carry Right Shift**  

<table>
<thead>
<tr>
<th>Byte</th>
<th>7</th>
<th>0</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Status Bits**  
N: Set if result is negative, reset if positive  
Z: Set if result is zero, reset otherwise  
C: Loaded from the LSB  
V: Set if initial destination is positive and initial carry is set, otherwise reset  

**Mode Bits**  
OSCOFF, CPUOFF, and GIE are not affected.  

**Example**  
R5 is shifted right one position. The MSB is loaded with 1.  
SETC ; Prepare carry for MSB  
RRC R5 ; R5/2 + 8000h → R5  

**Example**  
R5 is shifted right one position. The MSB is loaded with 1.  
SETC ; Prepare carry for MSB  
RRC.B R5 ; R5/2 + 80h → R5; low byte of R5 is used
**SBC.[W]** Subtract source and borrow/.NOT. carry from destination

**SBC.B** Subtract source and borrow/.NOT. carry from destination

**Syntax**

```
SBC    dst       or       SBC.W    dst
SBC.B  dst
```

**Operation**

```
dst + 0FFFFh + C -> dst
dst + 0FFh + C -> dst
```

**Emulation**

```
SUBC  #0,dst
SUBC.B #0,dst
```

**Description**
The carry bit (C) is added to the destination operand minus one. The previous contents of the destination are lost.

**Status Bits**

- **N:** Set if result is negative, reset if positive
- **Z:** Set if result is zero, reset otherwise
- **C:** Set if there is a carry from the MSB of the result, reset otherwise.
  - Set to 1 if no borrow, reset if borrow.
- **V:** Set if an arithmetic overflow occurs, reset otherwise.

**Mode Bits**

OSCOFF, CPUOFF, and GIE are not affected.

**Example**
The 16-bit counter pointed to by R13 is subtracted from a 32-bit counter pointed to by R12.

```
SUB   @R13,0(R12)  ; Subtract LSDs
SBC   2(R12)      ; Subtract carry from MSD
```

**Example**
The 8-bit counter pointed to by R13 is subtracted from a 16-bit counter pointed to by R12.

```
SUB.B @R13,0(R12) ; Subtract LSDs
SBC.B 1(R12)      ; Subtract carry from MSD
```

**Note:** **Borrow Implementation.**
The borrow is treated as a .NOT. carry:

<table>
<thead>
<tr>
<th>Borrow</th>
<th>Carry bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yes</td>
<td>0</td>
</tr>
<tr>
<td>No</td>
<td>1</td>
</tr>
</tbody>
</table>
* SETC  Set carry bit

Syntax  SETC

Operation  1 → C

Emulation  BIS    #1,SR

Description  The carry bit (C) is set.

Status Bits  N:  Not affected
Z:  Not affected
C:  Set
V:  Not affected

Mode Bits  OSCOFF, CPUOFF, and GIE are not affected.

Example  Emulation of the decimal subtraction:
Subtract R5 from R6 decimally
Assume that R5 = 03987h and R6 = 04137h

DSUB  ADD    #06666h,R5 ; Move content R5 from 0–9 to 6–0Fh
; R5 = 03987h + 06666h = 09FEDh
INV    R5    ; Invert this (result back to 0–9)
; R5 = .NOT. R5 = 06012h
SETC   ; Prepare carry = 1
DADD   R5,R6 ; Emulate subtraction by addition of:
; (010000h – R5 – 1)
; R6 = R6 + R5 + 1
; R6 = 0150h
**Instruction Set**

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>* SETN</td>
<td>Set negative bit</td>
</tr>
</tbody>
</table>

**Syntax**

```
SETN
```

**Operation**

```
1 -> N
```

**Emulation**

```
BIS #4,SR
```

**Description**
The negative bit (N) is set.

**Status Bits**

- **N**: Set
- **Z**: Not affected
- **C**: Not affected
- **V**: Not affected

**Mode Bits**

OSCOFF, CPUOFF, and GIE are not affected.
* SETZ  Set zero bit

Syntax  SETZ

Operation  1 -> Z

Emulation  BIS   #2,SR

Description  The zero bit (Z) is set.

Status Bits
N:  Not affected
Z:  Set
C:  Not affected
V:  Not affected

Mode Bits  OSCOFF, CPUOFF, and GIE are not affected.
Instruction Set

SUB[W]  Subtract source from destination
SUB.B   Subtract source from destination

Syntax

SUB src,dst or SUB.W src,dst
SUB.B src,dst

Operation
dst + .NOT.src + 1 → dst
or
[(dst – src → dst)]

Description
The source operand is subtracted from the destination operand by adding the
source operand’s 1s complement and the constant 1. The source operand is
not affected. The previous contents of the destination are lost.

Status Bits
N: Set if result is negative, reset if positive
Z: Set if result is zero, reset otherwise
C: Set if there is a carry from the MSB of the result, reset otherwise.
   Set to 1 if no borrow, reset if borrow.
V: Set if an arithmetic overflow occurs, otherwise reset

Mode Bits
OSCOFF, CPUOFF, and GIE are not affected.

Example
See example at the SBC instruction.

Example
See example at the SBC.B instruction.

Note: Borrow Is Treated as a .NOT.
The borrow is treated as a .NOT. carry:

<table>
<thead>
<tr>
<th>Borrow</th>
<th>Carry bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yes</td>
<td>0</td>
</tr>
<tr>
<td>No</td>
<td>1</td>
</tr>
</tbody>
</table>
SUBC[.W]SBB[.W] Subtract source and borrow/.NOT. carry from destination
SUBC.B,SBB.B Subtract source and borrow/.NOT. carry from destination

Syntax

| SUBC src,dst | SUBC.W src,dst or
| SBB src,dst | SBB.W src,dst
| SUBC.B src,dst | SBB.B src,dst |

Operation
dst + .NOT.src + C -> dst
or
(dst – src – 1 + C -> dst)

Description
The source operand is subtracted from the destination operand by adding the source operand’s 1s complement and the carry bit (C). The source operand is not affected. The previous contents of the destination are lost.

Status Bits
N: Set if result is negative, reset if positive.
Z: Set if result is zero, reset otherwise.
C: Set if there is a carry from the MSB of the result, reset otherwise.
V: Set if an arithmetic overflow occurs, reset otherwise.

Mode Bits
OSCOFF, CPUOFF, and GIE are not affected.

Example
Two floating point mantissas (24 bits) are subtracted. LSBs are in R13 and R10, MSBs are in R12 and R9.

| SUB.W R13,R10 | 16-bit part, LSBs
| SUBC.B R12,R9 | 8-bit part, MSBs |

Example
The 16-bit counter pointed to by R13 is subtracted from a 16-bit counter in R10 and R11(MSD).

| SUB.B @R13+,R10 | Subtract LSDs without carry |
| SUBC.B @R13,R11 | Subtract MSDs with carry |
| ... | resulting from the LSDs |

Note: Borrow Implementation
The borrow is treated as a .NOT. carry:

<table>
<thead>
<tr>
<th>Borrow</th>
<th>Carry bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yes</td>
<td>0</td>
</tr>
<tr>
<td>No</td>
<td>1</td>
</tr>
</tbody>
</table>
**Instruction Set**

**SWPB**  
Swap bytes

**Syntax**  
SWPB dst

**Operation**  
Bits 15 to 8 <-> bits 7 to 0

**Description**  
The destination operand high and low bytes are exchanged as shown in Figure 3–18.

**Status Bits**  
Status bits are not affected.

**Mode Bits**  
OSCOFF, CPUOFF, and GIE are not affected.

*Figure 3–18. Destination Operand Byte Swap*

**Example**

MOV #040BFh,R7 ; 0100000010111111 -> R7
SWPB R7 ; 1011111101000000 in R7

**Example**

The value in R5 is multiplied by 256. The result is stored in R5,R4.

SWPB R5
MOV R5,R4 ; Copy the swapped value to R4
BIC #0FF00h,R5 ; Correct the result
BIC #00FFh,R4 ; Correct the result
**SXT**

Extend Sign

**Syntax**

SXT  dst

**Operation**

Bit 7 $\rightarrow$ Bit 8 ........ Bit 15

**Description**

The sign of the low byte is extended into the high byte as shown in Figure 3–19.

**Status Bits**

- **N**: Set if result is negative, reset if positive
- **Z**: Set if result is zero, reset otherwise
- **C**: Set if result is not zero, reset otherwise (.NOT. Zero)
- **V**: Reset

**Mode Bits**

OSCOFF, CPUOFF, and GIE are not affected.

*Figure 3–19. Destination Operand Sign Extension*

```
Example

R7 is loaded with the P1IN value. The operation of the sign-extend instruction expands bit 8 to bit 15 with the value of bit 7.
R7 is then added to R6.

MOV .B &P1IN,R7 ; P1IN = 080h: . . . . . . 1000 0000
SXT R7 ; R7 = 0FF80h: 1111 1111 1000 0000
```
### Instruction Set

| * TST[.W] | Test destination |
| * TST.B | Test destination |

**Syntax**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TST dst or TST.W dst</td>
<td>dst + 0FFFFh + 1</td>
</tr>
<tr>
<td>TST.B dst</td>
<td>dst + 0FFh + 1</td>
</tr>
</tbody>
</table>

**Operation**

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMP #0,dst</td>
<td>cmp #0,dst</td>
</tr>
<tr>
<td>CMP.B #0,dst</td>
<td>cmp #0,dst</td>
</tr>
</tbody>
</table>

**Emulation**

<table>
<thead>
<tr>
<th>Emulation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N: Set if destination is negative, reset if positive</td>
<td>N: Set if destination is negative, reset if positive</td>
</tr>
<tr>
<td>Z: Set if destination contains zero, reset otherwise</td>
<td>Z: Set if destination contains zero, reset otherwise</td>
</tr>
<tr>
<td>C: Set</td>
<td>C: Set</td>
</tr>
<tr>
<td>V: Reset</td>
<td>V: Reset</td>
</tr>
</tbody>
</table>

**Mode Bits**

OSCOFF, CPUOFF, and GIE are not affected.

**Example**

R7 is tested. If it is negative, continue at R7NEG; if it is positive but not zero, continue at R7POS.

```assembly
TST R7 ; Test R7
JN R7NEG ; R7 is negative
JZ R7ZERO ; R7 is zero
R7POS ...... ; R7 is positive but not zero
R7NEG ...... ; R7 is negative
R7ZERO ...... ; R7 is zero
```

**Example**

The low byte of R7 is tested. If it is negative, continue at R7NEG; if it is positive but not zero, continue at R7POS.

```assembly
TST.B R7 ; Test low byte of R7
JN R7NEG ; Low byte of R7 is negative
JZ R7ZERO ; Low byte of R7 is zero
R7POS ...... ; Low byte of R7 is positive but not zero
R7NEG ...... ; Low byte of R7 is negative
R7ZERO ...... ; Low byte of R7 is zero
```
### XOR.W
- **Syntax**: `XOR src, dst` or `XOR.W src, dst`
- **Description**: The source and destination operands are exclusive ORed. The result is placed into the destination. The source operand is not affected.

### XOR.B
- **Syntax**: `XOR.B src, dst`
- **Description**: Exclusive OR of source with destination

### Modes
- **Mode Bits**: `OSCOFF`, `CPUOFF`, and `GIE` are not affected.

### Status Bits
- **N**: Set if result MSB is set, reset if not set
- **Z**: Set if result is zero, reset otherwise
- **C**: Set if result is not zero, reset otherwise ( = .NOT. Zero)
- **V**: Not specified

### Examples
1. **Example**: The bits set in R6 toggle the bits in the RAM word `TONI`.
   ```assembly
   XOR R6, TONI ; Toggle bits of word `TONI` on the bits set in `R6`
   ```
2. **Example**: The bits set in R6 toggle the bits in the RAM byte `TONI`.
   ```assembly
   XOR.B R6, TONI ; Toggle bits of byte `TONI` on the bits set in low byte of `R6`
   ```
3. **Example**: Reset to 0 those bits in low byte of `R7` that are different from bits in RAM byte `EDE`.
   ```assembly
   XOR.B EDE, R7 ; Set different bit to “1s”
   INV.B R7 ; Invert Lowbyte, Highbyte is 0h
   ```
3.4.4 Instruction Cycles and Lengths

The number of CPU clock cycles required for an instruction depends on the instruction format and the addressing modes used - not the instruction itself. The number of clock cycles refers to the MCLK.

Interrupt and Reset Cycles

Table 3–14 lists the CPU cycles for interrupt overhead and reset.

Table 3–14. Interrupt and Reset Cycles

<table>
<thead>
<tr>
<th>Action</th>
<th>No. of Cycles</th>
<th>Length of Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Return from interrupt (RETI)</td>
<td>5</td>
<td>1</td>
</tr>
<tr>
<td>Interrupt accepted</td>
<td>6</td>
<td>–</td>
</tr>
<tr>
<td>WDT reset</td>
<td>4</td>
<td>–</td>
</tr>
<tr>
<td>Reset (RST/NMI)</td>
<td>4</td>
<td>–</td>
</tr>
</tbody>
</table>

Format-II (Single Operand) Instruction Cycles and Lengths

Table 3–15 lists the length and CPU cycles for all addressing modes of format-II instructions.

Table 3–15. Format-II Instruction Cycles and Lengths

<table>
<thead>
<tr>
<th>Addressing Mode</th>
<th>RRA, RRC</th>
<th>SWPB, SXT</th>
<th>PUSH</th>
<th>CALL</th>
<th>Length of Instruction</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rn</td>
<td>1</td>
<td>3</td>
<td>4</td>
<td>1</td>
<td>1</td>
<td>SWPB R5</td>
</tr>
<tr>
<td>@Rn</td>
<td>3</td>
<td>4</td>
<td>4</td>
<td>1</td>
<td>1</td>
<td>RRC @R9</td>
</tr>
<tr>
<td>@Rn+</td>
<td>3</td>
<td>4</td>
<td>5</td>
<td>1</td>
<td>1</td>
<td>SWPB @R10+</td>
</tr>
<tr>
<td>#N</td>
<td>(See note)</td>
<td>4</td>
<td>5</td>
<td>2</td>
<td>2</td>
<td>CALL #81H</td>
</tr>
<tr>
<td>X(Rn)</td>
<td>4</td>
<td>5</td>
<td>5</td>
<td>2</td>
<td>2</td>
<td>CALL 2(R7)</td>
</tr>
<tr>
<td>EDE</td>
<td>4</td>
<td>5</td>
<td>5</td>
<td>2</td>
<td>2</td>
<td>PUSH EDE</td>
</tr>
<tr>
<td>&amp;EDE</td>
<td>4</td>
<td>5</td>
<td>5</td>
<td>2</td>
<td>2</td>
<td>SXT &amp;EDE</td>
</tr>
</tbody>
</table>

Note: Instruction Format II Immediate Mode

Do not use instructions RRA, RRC, SWPB, and SXT with the immediate mode in the destination field. Use of these in the immediate mode results in an unpredictable program operation.

Format-III (Jump) Instruction Cycles and Lengths

All jump instructions require one code word, and take two CPU cycles to execute, regardless of whether the jump is taken or not.
Format-I (Double Operand) Instruction Cycles and Lengths

Table 3-16 lists the length and CPU cycles for all addressing modes of format-I instructions.

Table 3-16. Format 1 Instruction Cycles and Lengths

<table>
<thead>

† Emulated Instruction
The basic clock module provides the clocks for MSP430x1xx devices. This chapter describes the operation of the basic clock module. The basic clock module is implemented in all MSP430x1xx devices.

4.1 Basic Clock Module Introduction

The basic clock module supports low system cost and ultralow-power consumption. Using three internal clock signals, the user can select the best balance of performance and low power consumption. The basic clock module can be configured to operate without any external components, with one external resistor, with one or two external crystals, or with resonators, under full software control.

The basic clock module includes two or three clock sources:

- **LFXT1CLK**: Low-frequency/high-frequency oscillator that can be used either with low-frequency 32,768-Hz watch crystals, or standard crystals, resonators, or external clock sources in the 450-kHz to 8-MHz range.

- **XT2CLK**: Optional high-frequency oscillator that can be used with standard crystals, resonators, or external clock sources in the 450-kHz to 8-MHz range.

- **DCOCLK**: Internal digitally controlled oscillator (DCO) with RC-type characteristics.

Three clock signals are available from the basic clock module:

- **ACLK**: Auxiliary clock. The ACLK is the buffered LFXT1CLK clock source divided by 1, 2, 4, or 8. ACLK is software selectable for individual peripheral modules.

- **MCLK**: Master clock. MCLK is software selectable as LFXT1CLK, XT2CLK (if available), or DCOCLK. MCLK is divided by 1, 2, 4, or 8. MCLK is used by the CPU and system.

- **SMCLK**: Sub-main clock. SMCLK is software selectable as LFXT1CLK, XT2CLK (if available), or DCOCLK. SMCLK is divided by 1, 2, 4, or 8. SMCLK is software selectable for individual peripheral modules.

The block diagram of the basic clock module is shown in Figure 4–1.
Figure 4–1. Basic Clock Block Diagram

Note: XT2 Oscillator

The XT2 Oscillator is not present on MSP430x11xx or MSP430x12xx devices. The LFXT1CLK is used in place of XT2CLK.
### 4.2 Basic Clock Module Operation

After a PUC, MCLK and SMCLK are sourced from DCOCLK at ~800 kHz (see device-specific datasheet for parameters) and ACLK is sourced from LFXT1 in LF mode.

Status register control bits SCG0, SCG1, OSCOFF, and CPUOFF configure the MSP430 operating modes and enable or disable portions of the basic clock module. See Chapter *System Resets, Interrupts and Operating Modes*. The DCOCTL, BCSCTL1, and BCSCTL2 registers configure the basic clock module.

The basic clock can be configured or reconfigured by software at any time during program execution, for example:

```
BIS.B #RSEL2+RSEL1+RSEL0,&BCSCTL1 ;
BIS.B #DCO2+DCO1+DCO0,&DCOCTL ; Set max DCO frequency
```

#### 4.2.1 Basic Clock Module Features for Low-Power Applications

Conflicting requirements typically exist in battery-powered MSP430x1xx applications:

- Low clock frequency for energy conservation and time keeping
- High clock frequency for fast reaction to events and fast burst processing capability

The basic clock module addresses the above conflicting requirements by allowing the user to select from the three available clock signals: ACLK, MCLK, and SMCLK. For optimal low-power performance, the ACLK can be configured to oscillate with a low-power 32,768-Hz watch crystal, providing a stable time base for the system and low power stand-by operation. The MCLK can be configured to operate from the on-chip DCO that can be only activated when requested by interrupt-driven events. The SMCLK can be configured to operate from a crystal or the DCO, depending on peripheral requirements. A flexible clock distribution and divider system is provided to fine tune the individual clock requirements.
4.2.2 LFXT1 Oscillator

The LFXT1 oscillator supports ultralow-current consumption using a 32,768-Hz watch crystal in LF mode (XTS = 0). A watch crystal connects to XIN and XOUT without any other external components. Internal 12-pF load capacitors are provided for LFXT1 in LF mode. The capacitors add serially, providing a match for standard 32,768-Hz crystals requiring a 6-pF load. Additional capacitors can be added if necessary.

The LFXT1 oscillator also supports high-speed crystals or resonators when in HF mode (XTS = 1). The high-speed crystal or resonator connects to XIN and XOUT and requires external capacitors on both terminals. These capacitors should be sized according to the crystal or resonator specifications.

LFXT1 may be used with an external clock signal on the XIN pin in either LF or HF mode. When used with an external signal, the external frequency must meet the datasheet parameters for the chosen mode.

Software can disable LFXT1 by setting OSCOFF, if this signal does not source SMCLK or MCLK, as shown in Figure 4–2.

Figure 4–2. Off Signals for the LFXT1 Oscillator

![Diagram of LFXT1 Oscillator Off Signals]

Note: LFXT1 Oscillator Characteristics

Low-frequency crystals often require hundreds of milliseconds to start up, depending on the crystal. It is recommended to leave the LFXT1 oscillator on when in LF mode.

Ultralow-power oscillators such as the LFXT1 in LF mode should be guarded from noise coupling from other sources. The crystal should be placed as close as possible to the MSP430 with the crystal housing grounded and the crystal traces guarded with ground traces.

The LFXT1 oscillator in LF mode requires a 5.1-MΩ resistor from XOUT to VSS when VCC < 2.5 V.
4.2.3 XT2 Oscillator

Some devices have a second crystal oscillator, XT2. XT2 sources XT2CLK and its characteristics are identical to LFXT1 in HF mode. The XT2OFF bit disables the XT2 oscillator if XT2CLK is not used for MCLK or SMCLK as shown in Figure 4–3.

XT may be used with external clock signals on the XT2IN pin. When used with an external signal, the external frequency must meet the datasheet parameters for XT2.

Figure 4–3. Off Signals for Oscillator XT2

4.2.4 Digitally-Controlled Oscillator (DCO)

The DCO is an integrated ring oscillator with RC-type characteristics. As with any RC-type oscillator, frequency varies with temperature, voltage, and from device to device. The DCO frequency can be adjusted by software using the DCOx, MODx, and RSELx bits. The digital control of the oscillator allows frequency stabilization despite its RC-type characteristics.

Disabling the DCO

Software can disable DCOCLK by setting SCG0 when it is not used to source SMCLK or MCLK in active mode, as shown in Figure 4–4.

Figure 4–4. On/Off Control of DCO
Adjusting the DCO frequency

After a PUC, the internal resistor is selected for the DC generator, RSELx = 4, and DCOx = 3, allowing the DCO to start at a mid-range frequency. MCLK and SMCLK are sourced from DCOCLK. Because the CPU executes code from MCLK, which is sourced from the fast-starting DCO, code execution begins from PUC in less than 6 µs. The typical DCOx and RSELx ranges and steps are shown in Figure 4–5.

The frequency of DCOCLK is set by the following functions:

- The current injected into the DC generator by either the internal or external resistor defines the fundamental frequency. The DCOR bit selects the internal or external resistor.

- The three RSELx bits select one of eight nominal frequency ranges for the DCO. These ranges are defined for an individual device in the device-specific data sheet.

- The three DCOx bits divide the DCO range selected by the RSELx bits into 8 frequency steps, separated by approximately 10%.

- The five MODx bits, switch between the frequency selected by the DCOx bits and the next higher frequency set by DCOx+1. When DCOx = 07h, the MODx bits have no effect because the DCO is already at the highest setting for the selected RSELx range.

**Figure 4–5. Typical DCOx Range and RSELx Steps**
Using an External Resistor ($R_{OSC}$) for the DCO

The DCO temperature coefficient can be reduced by using an external resistor $R_{OSC}$ to source the current for the DC generator. Figure 4–6 shows the typical relationship of $f_{DCO}$ vs. temperature for both the internal and external resistor options. Using an external $R_{OSC}$ reduces the DCO temperature coefficient to approximately $-0.05%/C$. See the device-specific data sheet for parameters.

$R_{OSC}$ also allows the DCO to operate at higher frequencies. For example, the internal resistor nominal value is approximately 200 kΩ, allowing the DCO to operate up to approximately 5 MHz. When using an external $R_{OSC}$ of approximately 100 kΩ the DCO can operate up to approximately 10 MHz. The user should take care to not exceed the maximum MCLK frequency specified in the datasheet, even though the DCO is capable of exceeding it.

Figure 4–6. DCO Frequency vs. Temperature
4.2.5 DCO Modulator

The modulator mixes two DCO frequencies, $f_{\text{DCO}}$ and $f_{\text{DCO}+1}$ to produce an intermediate effective frequency between $f_{\text{DCO}}$ and $f_{\text{DCO}+1}$ and spread the clock energy, reducing electromagnetic interference (EMI). The modulator mixes $f_{\text{DCO}}$ and $f_{\text{DCO}+1}$ for 32 DCOCCLK clock cycles and is configured with the MODx bits. When MODx = 0 the modulator is off.

The modulator mixing formula is:

$$t = (32 - \text{MODx}) \times t_{\text{DCO}} + \text{MODx} \times t_{\text{DCO}+1}$$

Because $f_{\text{DCO}}$ is lower than the effective frequency and $f_{\text{DCO}+1}$ is higher than the effective frequency, the error of the effective frequency integrates to zero. It does not accumulate. The error of the effective frequency is zero every 32 DCOCCLK cycles. Figure 4–7 illustrates the modulator operation.

The modulator settings and DCO control are configured with software. The DCOCCLK can be compared to a stable frequency of known value and adjusted with the DCOx, RSELx, and MODx bits. See http://www.ti.com/sc/msp430 for application notes and example code on configuring the DCO.

Figure 4–7. Modulator Patterns
### 4.2.6 Basic Clock Module Fail-Safe Operation

The basic clock module incorporates an oscillator-fault detection fail-safe feature. The oscillator fault detector is an analog circuit that monitors the LFXT1CLK (in HF mode) and the XT2CLK. An oscillator fault is detected when either clock signal is not present for approximately 50 µs. When an oscillator fault is detected, and when MCLK is sourced from either LFXT1 in HF mode or XT2, MCLK is automatically switched to the DCO for its clock source. This allows code execution to continue, even though the crystal oscillator has stopped.

When OFIFG is set and OFIE is set, an NMI interrupt is requested. The NMI interrupt service routine can test the OFIFG flag to determine if an oscillator fault occurred. The OFIFG flag must be cleared by software.

**Note: No Oscillator Fault Detection for LFXT1 in LF Mode**

Oscillator fault detection is only applicable for LFXT1 in HF mode and XT2. There is no oscillator fault detection for LFXT1 in LF mode.

OFIFG is set by the oscillator fault signal, XT_OscFault. XT_OscFault is set at POR, when LFXT1 has an oscillator fault in HF mode, or when XT2 has an oscillator fault. When XT2 or LFXT1 in HF mode is stopped with software the XT_OscFault signal becomes active immediately, remains active until the oscillator is re-started, and becomes inactive approximately 50 µs after the oscillator re-starts as shown in Figure 4–8.

*Figure 4–9. Oscillator-Fault Signal*
Oscillator Fault Detection

Signal XT_OscFault triggers the OFIFG flag as shown in Figure 4–10. The LFXT1_OscFault signal is low when LFXT1 is in LF mode.

On devices without XT2, the OFIFG flag cannot be cleared when LFXT1 is in LF mode. MCLK may be sourced by LFXT1CLK in LF mode by setting the SELMx bits, even though OFIFG remains set.

On devices with XT2, the OFIFG flag can be cleared by software when LFXT1 is in LF mode and it remains cleared. MCLK may be sourced by LFXT1CLK in LF mode regardless of the state of the OFIFG flag.

Figure 4–10. Oscillator-Fault-Interrupt

XT2 is an internal signal. XT2 = 0 on devices without XT2 (MSP430x11xx and MSP430x12xx). XT2 = 1 on devices with XT2 (MSP430F13x, MSP430F14x, MSP430F15x, and MSP430F16x)

IRQA: Interrupt request accepted

LFXT1_OscFault: Only applicable to LFXT1 oscillator in HF mode.
Sourcing MCLK from a Crystal

After a PUC, the basic clock module uses DCOCLK for MCLK. If required, MCLK may be sourced from LFXT1 or XT2.

The sequence to switch the MCLK source from the DCO clock to the crystal clock (LFXT1CLK or XT2CLK) is:

1) Switch on the crystal oscillator
2) Clear the OFIFG flag
3) Wait at least 50 μs
4) Test OFIFG, and repeat steps 1-4 until OFIFG remains cleared.

; Select LFXT1 (HF mode) for MCLK
BIC    #OSCOFF,SR       ; Turn on osc.
BIS.B #XTS,BCSCTL1     ; HF mode
L1 BIC.B #OFIFG,&IFG1  ; Clear OFIFG
MOV    #0FFh,R15        ; Delay
L2 DEC R15             ;
JNZ    L2               ;
BIT.B #OFIFG,&IFG1      ; Re-test OFIFG
JNZ    L1               ; Repeat test if needed
BIS.B #SELM1+SELM0,&BCSCTL2 ; Select LFXT1CLK
4.2.7 Synchronization of Clock Signals

When switching MCLK or SMCLK from one clock source to the another, the switch is synchronized to avoid critical race conditions as shown in Figure 4–11:

1) The current clock cycle continues until the next rising edge.
2) The clock remains high until the next rising edge of the new clock.
3) The new clock source is selected and continues with a full high period.

Figure 4–11. Switch MCLK from DCOCLK to LFXT1CLK
4.3 Basic Clock Module Registers

The basic clock module registers are listed in Table 4–1:

5.1 Flash Memory Introduction

The MSP430 flash memory is bit-, byte-, and word-addressable and programmable. The flash memory module has an integrated controller that controls programming and erase operations. The controller has three registers, a timing generator, and a voltage generator to supply program and erase voltages.

MSP430 flash memory features include:

- Internal programming voltage generation
- Bit, byte or word programmable
- Ultralow-power operation
- Segment erase and mass erase

The block diagram of the flash memory and controller is shown in Figure 5–1.

**Note: Minimum V\textsubscript{CC} During Flash Write or Erase**

The minimum V\textsubscript{CC} voltage during a flash write or erase operation is 2.7 V. If V\textsubscript{CC} falls below 2.7 V during a write or erase, the result of the write or erase will be unpredictable.

---

*Figure 5–1. Flash Memory Module Block Diagram*
5.2 Flash Memory Segmentation

MSP430 flash memory is partitioned into segments. Single bits, bytes, or words can be written to flash memory, but the segment is the smallest size of flash memory that can be erased. Three erase modes provide the ability to erase a single segment, erase all main segments, or erase all segments (main and information segments).

The flash memory is partitioned into main and information memory sections. There is no difference in the operation of the main and information memory sections. Code or data can be located in either section. The differences between the two sections are the segment size and the physical addresses.

The information memory has two 128-byte segments (MSP430x1101 devices have only one). The main memory has two or more 512-byte segments. See the device-specific datasheet for the complete memory map of a device.

Figure 5–2 shows the flash segmentation using an example of 4-KB flash that has eight main segments and both information segments.

Figure 5–2. Flash Memory Segments, 4-KB Example
5.3 Flash Memory Operation

The default mode of the flash memory is read mode. In read mode, the flash memory is not being erased or written, the flash timing generator and voltage generator are off, and the memory operates identically to ROM.

MSP430 flash memory is in-system programmable (ISP) without the need for additional external voltage. The CPU can program its own flash memory. The flash memory write/erase modes are selected with the BLKWRT, WRT, MERAS, and ERASE bits and are:

- Byte/word write
- Block write
- Segment Erase
- Mass Erase (all main memory segments)
- All Erase (all segments)

Reading or writing to flash memory while it is being programmed or erased is prohibited. If CPU execution is required during the write or erase, the code to be executed must be in RAM. Any flash update can be initiated from within flash memory or RAM.

5.3.1 Flash Memory Timing Generator

Write and erase operations are controlled by the flash timing generator shown in Figure 5–3. The flash timing generator operating frequency, \( f_{(FTG)} \), must be in the range from ~ 257 kHz to ~ 476 kHz (see device-specific datasheet).

Figure 5–3. Flash Memory Timing Generator Block Diagram

The flash timing generator can be sourced from ACLK, SMCLK, or MCLK. The selected clock source should be divided using the FNx bits to meet the frequency requirements for \( f_{(FTG)} \). If the \( f_{(FTG)} \) frequency deviates from the specification during the write or erase operation, the result of the write or erase may be unpredictable, or the flash memory may be stressed above the limits of reliable operation.
5.3.2 Erasing Flash Memory

The erased level of a flash memory bit is 1. Each bit can be programmed from 1 to 0 individually but to reprogram from 0 to 1 requires an erase cycle. The smallest amount of flash that can be erased is a segment. There are three erase modes selected with the ERASE and MERAS bits listed in Table 5–1.

Table 5–1. Erase Modes

<table>
<thead>
<tr>
<th>MERAS</th>
<th>ERASE</th>
<th>Erase Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>Segment erase</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Mass erase (all main memory segments)</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Erase all flash memory (main and information segments)</td>
</tr>
</tbody>
</table>

Any erase is initiated by a dummy write into the address range to be erased. The dummy write starts the flash timing generator and the erase operation. Figure 5–4 shows the erase cycle timing. The BUSY bit is set immediately after the dummy write and remains set throughout the erase cycle. BUSY, MERAS, and ERASE are automatically cleared when the cycle completes. The erase cycle timing is not dependent on the amount of flash memory present on a device. Erase cycle times are equivalent for all MSP430 devices.

Figure 5–4. Erase Cycle Timing

A dummy write to an address not in the range to be erased does not start the erase cycle, does not affect the flash memory, and is not flagged in any way. This errant dummy write is ignored.

Interrupts should be disabled before a flash erase cycle. After the erase cycle has completed, interrupts may be re-enabled. Any interrupt that occurred during the erase cycle will have its associated flag set, and will generate an interrupt request when re-enabled.
Initiating an Erase from Within Flash Memory

Any erase cycle can be initiated from within flash memory or from RAM. When a flash segment erase operation is initiated from within flash memory, all timing is controlled by the flash controller, and the CPU is held while the erase cycle completes. After the erase cycle completes, the CPU resumes code execution with the instruction following the dummy write.

When initiating an erase cycle from within flash memory, it is possible to erase the code needed for execution after the erase. If this occurs, CPU execution will be unpredictable after the erase cycle.

The flow to initiate an erase from flash is shown in Figure 5–5.

Figure 5–5. Erase Cycle from Within Flash Memory

; Segment Erase from flash. 514 kHz < SMCLK < 952 kHz
; Assumes ACCVIE = NMIIE = OFIE = 0.
MOV #WDTPW+WDTHOLD,&WDTCTL ; Disable WDT
DINT ; Disable interrupts
MOV #FWKEY+FSSEL1+FN0,&FCTL2 ; SMCLK/2
MOV #FWKEY,&FCTL3 ; Clear LOCK
MOV #FWKEY+ERASE,&FCTL1 ; Enable segment erase
CLR &0FC10h ; Dummy write, erase S1
MOV #FWKEY+LOCK,&FCTL3 ; Done, set LOCK
... ; Re-enable WDT?
EINT ; Enable interrupts
Initiating an Erase from RAM

Any erase cycle may be initiated from RAM. In this case, the CPU is not held and can continue to execute code from RAM. The BUSY bit must be polled to determine the end of the erase cycle before the CPU can access any flash address again. If a flash access occurs while BUSY=1, it is an access violation, ACCVIFG will be set, and the erase results will be unpredictable.

The flow to initiate an erase from flash from RAM is shown in Figure 5–6.

**Figure 5–6. Erase Cycle from Within RAM**

```
Disable all interrupts and watchdog

BUSY = 1

yes

Setup flash controller and erase mode

Dummy write

BUSY = 1

yes

Set LOCK = 1, re-enable interrupts and watchdog

; Segment Erase from RAM. 514 kHz < SMCLK < 952 kHz
; Assumes ACCVIE = NMIIE = OFIE = 0.
    MOV  #WDTPW+WDTHOLD,&WDTCTL ; Disable WDT
    DINT ; Disable interrupts
    L1  BIT  #BUSY,&FCTL3 ; Test BUSY
         JNZ  L1 ; Loop while busy
    MOV  #FWKEY+FSSEL1+FN0,&FCTL2 ; SMCLK/2
    MOV  #FWKEY,&FCTL3 ; Clear LOCK
    MOV  #FWKEY+ERASE,&FCTL1 ; Enable erase
    CLR  &0FC10h ; Dummy write, erase S1
    L2  BIT  #BUSY,&FCTL3 ; Test BUSY
         JNZ  L2 ; Loop while busy
    MOV  #FWKEY+LOCK,&FCTL3 ; Done, set LOCK
         ... ; Re-enable WDT?
    EINT ; Enable interrupts
```
5.3.3 Writing Flash Memory

The write modes, selected by the WRT and BLKWRT bits, are listed in Table 5–1.

**Table 5–2. Write Modes**

<table>
<thead>
<tr>
<th>BLKWRT</th>
<th>WRT</th>
<th>Write Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>Byte/word write</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Block write</td>
</tr>
</tbody>
</table>

Both write modes use a sequence of individual write instructions, but using the block write mode is approximately twice as fast as byte/word mode, because the voltage generator remains on for the complete block write. Any instruction that modifies a destination can be used to modify a flash location in either byte/word write mode or block write mode.

The BUSY bit is set while a write operation is active and cleared when the operation completes. If the write operation is initiated from RAM, the CPU must not access flash while BUSY=1. Otherwise, an access violation occurs, ACCVIFG is set, and the flash write is unpredictable.

### Byte/Word Write

A byte/word write operation can be initiated from within flash memory or from RAM. When initiating from within flash memory, all timing is controlled by the flash controller, and the CPU is held while the write completes. After the write completes, the CPU resumes code execution with the instruction following the write. The byte/word write timing is shown in Figure 5–7.

#### Figure 5–7. Byte/Word Write Timing

![Byte/Word Write Timing Diagram](image)

When a byte/word write is executed from RAM, the CPU continues to execute code from RAM. The BUSY bit must be zero before the CPU accesses flash again, otherwise an access violation occurs, ACCVIFG is set, and the write result is unpredictable.
Initiating a Byte/Word Write from Within Flash Memory

The flow to initiate a byte/word write from flash is shown in Figure 5–8.

Figure 5–8. Initiating a Byte/Word Write from Flash

```
; Byte/word write from flash. 514 kHz < SMCLK < 952 kHz
; Assumes 0FF1Eh is already erased
; Assumes ACCVIE = NMIIE = OFIE = 0.
MOV  #0FF1Eh+&FCTL2 ; SMCLK/2
MOV  #0FF1Eh+&FCTL3 ; Clear LOCK
MOV  #0FF1Eh+&FCTL1 ; Enable write
MOV  #0123h+&WDTCTL ; Disable WDT
DINT ; Disable interrupts
MOV  #0123h+&FCTL1 ; 0123h -> 0FF1Eh
MOV  #0FF1Eh+&FCTL2 ; Done. Clear WRT
MOV  #0FF1Eh+&FCTL3 ; Set LOCK
... ; Re-enable WDT?
EINT ; Enable interrupts
```
Initiating a Byte/Word Write from RAM

The flow to initiate a byte/word write from RAM is shown in Figure 5–9.

Figure 5–9. Initiating a Byte/Word Write from RAM

; Byte/word write from RAM. 514 kHz < SMCLK < 952 kHz
; Assumes 0FF1Eh is already erased
; Assumes ACCVIE = NMIIE = OFIE = 0.
MOV #WDTPW+WDTHOLD,&WDTCTL ; Disable WDT
DINT ; Disable interrupts
L1 BIT #BUSY,&FCTL3 ; Test BUSY
JNZ L1 ; Loop while busy
MOV #FWKEY+FSSEL1+FN0,&FCTL2 ; SMCLK/2
MOV #FWKEY,&FCTL3 ; Clear LOCK
MOV #FWKEY+WRT,&FCTL1 ; Enable write
MOV #0123h,&0FF1Eh ; 0123h -> 0FF1Eh
L2 BIT #BUSY,&FCTL3 ; Test BUSY
JNZ L2 ; Loop while busy
MOV #FWKEY,&FCTL1 ; Clear WRT
MOV #FWKEY+LOCK,&FCTL3 ; Set LOCK
... ; Re-enable WDT?
EINT ; Enable interrupts
Block Write

The block write can be used to accelerate the flash write process when many sequential bytes or words need to be programmed. A block is 64 bytes, starting at 0x000h, 0x400h, 0x800h, or 0xC00h, and ending at 0x3Fh, 0x7Fh, 0xBFh, or 0xFFh as shown in Figure 5–10. The flash programming voltage remains on for the duration of writing the 64-byte block.

Figure 5–10. Flash Memory Blocks

A block write cannot be initiated from within flash memory. The block write must be initiated from RAM only. The BUSY bit remains set throughout the duration of the block write. The WAIT bit must be checked between writing each byte or word in the block. When WAIT is set the next byte or word of the block can be written. When writing successive blocks, the BLKWRT bit must be cleared after the current block is complete. BLKWRT can be set initiating the next block write after the required flash recovery time given by t(end). BUSY is cleared following each block write completion indicating the next block can be written. Figure 5–11 shows the block write timing.

Figure 5–11. Block-Write Cycle Timing
Block Write Flow and Example

A block write flow is shown in Figure 5–8 and the following example.

Figure 5–12. Block Write Flow

1. Disable all interrupts and watchdog
2. If BUSY = 1, go back and disable all interrupts and watchdog.
3. Setup flash controller
4. If BLKWRT = WRT = 1, proceed with write byte or word.
5. Write byte or word
6. If WAIT = 0, go to Step 4.
7. If Block Border = yes, go to Step 8.
8. Set BLKWRT = 0
9. If BUSY = 1, go back and disable all interrupts and watchdog.
10. If Another Block = yes, set WRT = 0, LOCK = 1, re-enable interrupts and WDT.
Write one block starting at 0F000h.
Must be executed from RAM, Assumes Flash is already erased.
514 kHz < SMCLK < 952 kHz
Assumes ACCVIE = NMIIE = OFIE = 0.

MOV #32,R5  ; Use as write counter
MOV #0F000h,R6  ; Write pointer
MOV #WDTPW+WDTHOLD,&WDTCTL  ; Disable WDT
DINT  ; Disable interrupts

L1 BIT #BUSY,&FCTL3  ; Test BUSY
JNZ L1  ; Loop while busy
MOV #FWKEY+FSSEL1+FN0,&FCTL2  ; SMCLK/2
MOV #FWKEY,&FCTL3  ; Clear LOCK
MOV #FWKEY+BLKWRT+WRT,&FCTL1  ; Enable block write

L2 MOV Write_Value,0(R6)  ; Write location

L3 BIT #WAIT,&FCTL3  ; Test WAIT
JZ L3  ; Loop while WAIT=0
INCD R6  ; Point to next word
DEC R5  ; Decrement write counter
JNZ L2  ; End of block?

MOV #FWKEY,&FCTL1  ; Clear WRT,BLKWRT
L4 BIT #BUSY,&FCTL3  ; Test BUSY
JNZ L4  ; Loop while busy
MOV #FWKEY+LOCK,&FCTL3  ; Set LOCK

...  ; Re-enable WDT if needed
EINT  ; Enable interrupts

Flash Memory Operation
5.3.4 Flash Memory Access During Write or Erase

When any write or any erase operation is initiated from RAM and while BUSY=1, the CPU may not read or write to or from any flash location. Otherwise, an access violation occurs, ACCVIFG is set, and the result is unpredictable. Also if a write to flash is attempted with WRT=0, the ACCVIFG interrupt flag is set, and the flash memory is unaffected.

When a byte/word write or any erase operation is initiated from within flash memory, the flash controller returns op-code 03FFFh to the CPU at the next instruction fetch. Op-code 03FFFh is the \texttt{JMP PC} instruction. This causes the CPU to loop until the flash operation is finished. When the operation is finished and BUSY=0, the flash controller allows the CPU to fetch the proper op-code and program execution resumes.

The flash access conditions while BUSY=1 are listed in Table 5–3.

\textbf{Table 5–3. Flash Access While BUSY = 1}

<table>
<thead>
<tr>
<th>Flash Operation</th>
<th>Flash Access</th>
<th>WAIT</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any erase, or Byte/word write</td>
<td>Read</td>
<td>0</td>
<td>ACCVIFG = 1. 03FFFh is the value read</td>
</tr>
<tr>
<td></td>
<td>Write</td>
<td>0</td>
<td>ACCVIFG = 1. Write is ignored</td>
</tr>
<tr>
<td></td>
<td>Instruction fetch</td>
<td>0</td>
<td>ACCVIFG = 0. CPU fetches 03FFFh. This is the \texttt{JMP PC} instruction.</td>
</tr>
</tbody>
</table>

| Block write | Any       | 0    | ACCVIFG = 1, LOCK = 1                      |
|            | Read      | 1    | ACCVIFG = 0, 03FFFh is the value read      |
|            | Write     | 1    | ACCVIFG = 0, Write is ignored             |
|            | Instruction fetch | 1 | ACCVIFG = 1, LOCK = 1                     |

All interrupt sources should be disabled before initiating any flash operation. If an enabled interrupt were to occur during a flash operation, the CPU would fetch 03FFFh as the address of the interrupt service routine. The CPU would then execute the \texttt{JMP PC} instruction while BUSY=1. When the flash operation finished, the CPU would begin executing code at address 03FFFh, not the correct address for interrupt service routine.
5.3.5 Stopping a Write or Erase Cycle

Any write or erase operation can be stopped before its normal completion by setting the emergency exit bit EMEX. Setting the EMEX bit stops the active operation immediately and stops the flash controller. All flash operations cease, the flash returns to read mode, and all bits in the FCTL1 register are reset. The result of the intended operation is unpredictable.

5.3.6 Configuring and Accessing the Flash Memory Controller

The FCTLx registers are 16-bit, password-protected, read/write registers. Any read or write access must use word instructions and write accesses must include the write password 0A5h in the upper byte. Any write to any FCTLx register with any value other than 0A5h in the upper byte is a security key violation, sets the KEYV flag and triggers a PUC system reset. Any read of any FCTLx registers reads 096h in the upper byte.

Any write to FCTL1 during an erase or byte/word write operation is an access violation and sets ACCVIFG. Writing to FCTL1 is allowed in block write mode when WAIT=1, but writing to FCTL1 in block write mode when WAIT=0 is an access violation and sets ACCVIFG.

Any write to FCTL2 when the BUSY=1 is an access violation.

Any FCTLx register may be read when BUSY=1. A read will not cause an access violation.

5.3.7 Flash Memory Controller Interrupts

The flash controller has two interrupt sources, KEYV, and ACCVIFG. ACCVIFG is set when an access violation occurs. When the ACCVIE bit is re-enabled after a flash write or erase, a set ACCVIFG flag will generate an interrupt request. ACCVIFG sources the NMI interrupt vector, so it is not necessary for GIE to be set for ACCVIFG to request an interrupt. ACCVIFG may also be checked by software to determine if an access violation occurred. ACCVIFG must be reset by software.

The key violation flag KEYV is set when any of the flash control registers are written with an incorrect password. When this occurs, a PUC is generated immediately resetting the device.

5.3.8 Programming Flash Memory Devices

There are three options for programming an MSP430 flash device. All options support in-system programming:

- Program via JTAG
- Program via the Bootstrap Loader
- Program via a custom solution
Programming Flash Memory via JTAG

MSP430 devices can be programmed via the JTAG port. The JTAG interface requires four signals (5 signals on 20- and 28-pin devices), ground and optionally V_{CC} and RST/NMI.

The JTAG port is protected with a fuse. Blowing the fuse completely disables the JTAG port and is not reversible. Further access to the device via JTAG is not possible For more details see the Application report Programming a Flash-Based MSP430 Using the JTAG Interface at www.ti.com/sc/msp430.

Programming Flash Memory via the Bootstrap loader (BSL)

Every MSP430 flash device contains a bootstrap loader. The BSL enables users to read or program the flash memory or RAM using a UART serial interface. Access to the MSP430 flash memory via the BSL is protected by a 256-bit, user-defined password. For more details see the Application report Features of the MSP430 Bootstrap Loader at www.ti.com/sc/msp430.

Programming Flash Memory via a Custom Solution

The ability of the MSP430 CPU to write to its own flash memory allows for in-system and external custom programming solutions as shown in Figure 5–13. The user can choose to provide data to the MSP430 through any means available (UART, SPI, etc.). User-developed software can receive the data and program the flash memory. Since this type of solution is developed by the user, it can be completely customized to fit the application needs for programming, erasing, or updating the flash memory.

Figure 5–13. User-Developed Programming Solution
5.4 Flash Memory Registers

The flash memory registers are listed in Table 5–4.

<td>FNx, Flash controller clock divider</td>
<td>FNx+1</td>
<td>FNx+1</td>
</tr>
</tbody>
</table>

**FWKEYx** Bits 15-8
- FCTLx password. Always read as 096h. Must be written as 0A5h or a PUC will be generated.

**FSSELx** Bits 7-6
- Flash controller clock source select:
  - 00 ACLK
  - 01 MCLK
  - 10 SMCLK
  - 11 SMCLK

**FNx** Bits 5-0
- Flash controller clock divider. These six bits select the divider for the flash controller clock. The divisor value is FNx + 1. For example, when FNx=00h, the divisor is 1. When FNx=03Fh the divisor is 64.

<td>6–7</td>
</tr>
</tbody>
</table>
6.1 SVS Introduction

The supply voltage supervisor (SVS) is used to monitor the AV\textsubscript{CC} supply voltage or an external voltage. The SVS can be configured to set a flag or generate a POR reset when the supply voltage or external voltage drops below a user-selected threshold.

The SVS features include:

- AV\textsubscript{CC} monitoring
- Selectable generation of POR
- Output of SVS comparator accessible by software
- Low-voltage condition latched and accessible by software
- 14 selectable threshold levels
- External channel to monitor external voltage

The SVS block diagram is shown in Figure 6–1.
Figure 6–1. SVS Block Diagram
6.2 SVS Operation

The SVS detects if the AV\textsubscript{CC} voltage drops below a selectable level. It can be configured to provide a POR or set a flag, when a low-voltage condition occurs. The SVS is disabled after a POR to conserve current consumption.

6.2.1 Configuring the SVS

The VLD\textsubscript{x} bits are used to enable/disable the SVS and select one of 14 threshold levels (V_{SVS, IT}) for comparison with AV\textsubscript{CC}. The SVS is off when VLD\textsubscript{x} = 0 and on when VLD\textsubscript{x} > 0. The SVSON bit does not turn on the SVS. Instead, it reflects the on/off state of the SVS and can be used to determine when the SVS is on.

When VLD\textsubscript{x} = 1111, the external SVSIN channel is selected. The voltage on SVSIN is compared to an internal level of approximately 1.2 V.

6.2.2 SVS Comparator Operation

A low-voltage condition exists when AV\textsubscript{CC} drops below the selected threshold or when the external voltage drops below its 1.2-V threshold. Any low-voltage condition sets the SVSFG bit.

The PORON bit enables or disables the device-reset function of the SVS. If PORON = 1, a POR is generated when SVSFG is set. If PORON = 0, a low-voltage condition sets SVSFG, but does not generate a POR.

The SVSFG bit is latched. This allows user software to determine if a low-voltage condition occurred previously. The SVSFG bit must be reset by user software. If the low-voltage condition is still present when SVSFG is reset, it will be immediately set again by the SVS.
6.2.3 Changing the VLDx Bits

When the VLDx bits are changed, two settling delays are implemented to allow the SVS circuitry to settle. During each delay, the SVS will not set SVSFG. The delays, \( t_d(SVS_{on}) \) and \( t_{settle} \), are shown in Figure 6–2. The \( t_d(SVS_{on}) \) delay takes affect when VLDx is changed from zero to any non-zero value and is approximately 50 \( \mu \text{s} \). The \( t_{settle} \) delay takes affect when the VLDx bits change from any non-zero value to any other non-zero value and is a maximum of \( \sim 12 \mu \text{s} \). See the device-specific datasheet for the delay parameters.

During the delays, the SVS will not flag a low-voltage condition or reset the device, and the SVSON bit is cleared. Software can test the SVSON bit to determine when the delay has elapsed and the SVS is monitoring the voltage properly.

*Figure 6–2. SVSON state When Changing VLDx*
6.2.4 SVS Operating Range

Each SVS level has hysteresis to reduce sensitivity to small supply voltage changes when AV<sub>CC</sub> is close to the threshold. The SVS operation and SVS/Brownout interoperation are shown in Figure 6–3.

Figure 6–3. Operating Levels for SVS and Brownout/Reset Circuit
6.3 SVS Registers

The SVS registers are listed in Table 6-1.

VLDx Bits 7-4
Voltage level detect. These bits turn on the SVS and select the nominal SVS threshold voltage level. See the device–specific datasheet for parameters.

0000 SVS is off
0001 1.9 V
0010 2.1 V
0011 2.2 V
0100 2.3 V
0101 2.4 V
0110 2.5 V
0111 2.65 V
1000 2.8 V
1001 2.9 V
1010 3.05
1011 3.2 V
1100 3.35 V
1101 3.5 V
1110 3.7 V
1111 Compares external input voltage SVSIN to 1.2 V.

PORON Bit 3
POR on. This bit enables the SVSFG flag to cause a POR device reset.
0 SVSFG does not cause a POR
1 SVSFG causes a POR

SVSON Bit 2
SVS on. This bit reflects the status of SVS operation. This bit DOES NOT turn on the SVS. The SVS is turned on by setting VLDx > 0.
0 SVS is Off
1 SVS is On

SVSOP Bit 1
SVS output. This bit reflects the output value of the SVS comparator.
0 SVS comparator output is high
1 SVS comparator output is low

SVSFG Bit 0
SVS flag. This bit indicates a low voltage condition. SVSFG remains set after a low voltage condition until reset by software.
0 No low voltage condition occurred
1 A low voltage condition is present or has occurred
This chapter describes the hardware multiplier. The hardware multiplier is implemented in MSP430x14x and MSP430x16x devices.

7.1 Hardware Multiplier Introduction

The hardware multiplier is a peripheral and is not part of the MSP430 CPU. This means, its activities do not interfere with the CPU activities. The multiplier registers are peripheral registers that are loaded and read with CPU instructions.

The hardware multiplier supports:

- Unsigned multiply
- Signed multiply
- Unsigned multiply accumulate
- Signed multiply accumulate
- 16×16 bits, 16×8 bits, 8×16 bits, 8×8 bits

The hardware multiplier block diagram is shown in Figure 7–1.

Figure 7–1. Hardware Multiplier Block Diagram
7.2 Hardware Multiplier Operation

The hardware multiplier supports unsigned multiply, signed multiply, unsigned multiply accumulate, and signed multiply accumulate operations. The type of operation is selected by the address the first operand is written to.

The hardware multiplier has two 16-bit operand registers, OP1 and OP2, and three result registers, RESLO, RESHI, and SUMEXT. RESLO stores the low word of the result, RESHI stores the high word of the result, and SUMEXT stores information about the result. The result is ready in three MCLK cycles and can be read with the next instruction after writing to OP2, except when using an indirect addressing mode to access the result. When using indirect addressing for the result, a NOP is required before the result is ready.

7.2.1 Operand Registers

The operand one register OP1 has four addresses, shown in Table 7–1, used to select the multiply mode. Writing the first operand to the desired address selects the type of multiply operation but does not start any operation. Writing the second operand to the operand two register OP2 initiates the multiply operation. Writing OP2 starts the selected operation with the values stored in OP1 and OP2. The result is written into the three result registers RESLO, RESHI, and SUMEXT.

Repeated multiply operations may be performed without reloading OP1 if the OP1 value is used for successive operations. It is not necessary to re-write the OP1 value to perform the operations.

Table 7–1. OP1 addresses

<table>

</tr>
<tr>
<td></td>
<td>00000h  Result was positive or zero</td>
</tr>
<tr>
<td></td>
<td>0FFFFh  Result was negative</td>
</tr>
</tbody>
</table>

**MACS Underflow and Overflow**

The multiplier does not automatically detect underflow or overflow in the MACS mode. The accumulator range for positive numbers is 0 to 7FFFF FFFFh and for negative numbers is 0FFFF FFFFh to 8000 0000h. An overflow occurs when the sum of two negative numbers yields a result that is in the range for a positive number. An underflow occurs when the sum of two positive numbers yields a result that is in the range for a negative number. In both of these cases, the SUMEXT register contains the correct sign of the result, 0FFFFh for overflow and 0000h for underflow. User software must detect and handle these conditions appropriately.
7.2.3 Software Examples

Examples for all multiplier modes follow. All 8x8 modes use the absolute address for the registers because the assembler will not allow .B access to word registers when using the labels from the standard definitions file.

; 16x16 Unsigned Multiply
  MOV #01234h,&MPY ; Load first operand
  MOV #05678h,&OP2 ; Load second operand
  ; ... ; Process results

; 8x8 Unsigned Multiply. Absolute addressing.
  MOV.B #012h,&0130h ; Load first operand
  MOV.B #034h,&0138h ; Load 2nd operand
  ; ... ; Process results

; 16x16 Signed Multiply
  MOV #01234h,&MPYS ; Load first operand
  MOV #05678h,&OP2 ; Load 2nd operand
  ; ... ; Process results

; 8x8 Signed Multiply. Absolute addressing.
  MOV.B #012h,&0132h ; Load first operand
  SXT &MPYS ; Sign extend first operand
  MOV.B #034h,&0138h ; Load 2nd operand
  SXT &OP2 ; Sign extend 2nd operand
  ; (triggers 2nd multiplication)
  ; ... ; Process results

; 16x16 Unsigned Multiply Accumulate
  MOV #01234h,&MAC ; Load first operand
  MOV #05678h,&OP2 ; Load 2nd operand
  ; ... ; Process results

; 8x8 Unsigned Multiply Accumulate. Absolute addressing
  MOV.B #012h,&0134h ; Load first operand
  MOV.B #034h,&0138h ; Load 2nd operand
  ; ... ; Process results

; 16x16 Signed Multiply Accumulate
  MOV #01234h,&MACS ; Load first operand
  MOV #05678h,&OP2 ; Load 2nd operand
  ; ... ; Process results

; 8x8 Signed Multiply Accumulate. Absolute addressing
  MOV.B #012h,&0136h ; Load first operand
  SXT &MACS ; Sign extend first operand
  MOV.B #034h,R5 ; Temp. location for 2nd operand
  SXT R5 ; Sign extend 2nd operand
  MOV R5,&OP2 ; Load 2nd operand
  ; ... ; Process results
7.2.4 Indirect Addressing of RESLO

When using indirect or indirect autoincrement addressing mode to access the result registers, at least one instruction is needed between loading the second operand and accessing one of the result registers:

; Access multiplier results with indirect addressing
MOV   #RESLO,R5    ; RESLO address in R5 for indirect
MOV   &OPER1,&MPY ; Load 1st operand
MOV   &OPER2,&OP2 ; Load 2nd operand
NOP   ; Need one cycle
MOV   @R5+,&xxx ; Move RESLO
MOV   @R5,&xxx ; Move RESHI

7.2.5 Using Interrupts

If an interrupt occurs after writing OP1, but before writing OP2, and the multiplier is used in servicing that interrupt, the original multiplier mode selection is lost and the results are unpredictable. To avoid this, disable interrupts before using the hardware multiplier or do not use the multiplier in interrupt service routines.

; Disable interrupts before using the hardware multiplier
DINT   ; Disable interrupts
NOP   ; Required for DINT
MOV   #xxh,&MPY ; Load 1st operand
MOV   #xxh,&OP2 ; Load 2nd operand
EINT   ; Interrupts may be enable before
; Process results
### 7.3 Hardware Multiplier Registers

The hardware multiplier registers are listed in Table 7–4.

The DMA controller module transfers data from one address to another without CPU intervention. This chapter describes the operation of the DMA controller. The DMA controller is implemented in MSP430x15x and MSP430x16x devices.

</tbody>
</table>
8.1 DMA Introduction

The direct memory access (DMA) controller transfers data from one address to another, without CPU intervention, across the entire address range. For example, the DMA controller can move data from the ADC12 conversion memory to RAM.

Using the DMA controller can increase the throughput of peripheral modules. It can also reduce system power consumption by allowing the CPU to remain in a low-power mode without having to awaken to move data to or from a peripheral.

The DMA controller features include:

- Three independent transfer channels
- Configurable DMA channel priorities
- Requires only two MCLK clock cycles
- Byte or word and mixed byte/word transfer capability
- Block sizes up to 65535 bytes or words
- Configurable transfer trigger selections
- Selectable edge or level-triggered transfer
- Four addressing modes
- Single, block, or burst-block transfer modes

The DMA controller block diagram is shown in Figure 8–1.
Figure 8–1. DMA Controller Block Diagram
8.2 DMA Operation

The DMA controller is configured with user software. The setup and operation of the DMA is discussed in the following sections.

8.2.1 DMA Addressing Modes

The DMA controller has four addressing modes. The addressing mode for each DMA channel is independently configurable. For example, channel 0 may transfer between two fixed addresses, while channel 1 transfers between two blocks of addresses. The addressing modes are shown in Figure 8–2. The addressing modes are:

- Fixed address to fixed address
- Fixed address to block of addresses
- Block of addresses to fixed address
- Block of addresses to block of addresses

The addressing modes are configured with the DMASRCINCRx and DMADSTINCRx control bits. The DMASRCINCRx bits select if the source address is incremented, decremented, or unchanged after each transfer. The DMADSTINCRx bits select if the destination address is incremented, decremented, or unchanged after each transfer.

Transfers may be byte-to-byte, word-to-word, byte-to-word, or word-to-byte. When transferring word-to-byte, only the lower byte of the source-word transfers. When transferring byte-to-word, the upper byte of the destination-word is cleared when the transfer occurs.

Figure 8–2. DMA Addressing Modes
### 8.2.2 DMA Transfer Modes

The DMA controller has six transfer modes selected by the DMADTx bits as listed in Table 8–1. Each channel is individually configurable for its transfer mode. For example, channel 0 may be configured in single transfer mode, while channel 1 is configured for burst-block transfer mode, and channel 2 operates in repeated block mode. The transfer mode is configured independently from the addressing mode. Any addressing mode can be used with any transfer mode.

<td>CPU activity is interleaved with a block transfer. DMAEN remains enabled.</td>
</tr>
</tbody>
</table>
Single Transfer

In single transfer mode, each byte/word transfer requires a separate trigger. The single transfer state diagram is shown in Figure 8–3.

The DMAxSZ register is used to define the number of transfers to be made. The DMADSTINCRx and DMASRCINCRx bits select if the destination address and the source address are incremented or decremented after each transfer. If DMAxSZ = 0, no transfers occur.

The DMAxSA, DMAxDA, and DMAxSZ registers are copied into temporary registers. The temporary values of DMAxSA and DMAxDA are incremented or decremented after each transfer. The DMAxSZ register is decremented after each transfer. When the DMAxSZ register decrements to zero it is reloaded from its temporary register and the corresponding DMAIFG flag is set. When DMADTx = 0, the DMAEN bit is cleared automatically when DMAxSZ decrements to zero and must be set again for another transfer to occur.

In repeated single transfer mode, the DMA controller remains enabled with DMAEN = 1, and a transfer occurs every time a trigger occurs.

  - DMAxSZ > 0 AND DMAEN = 1

- **T_Size → DMAxSZ**
  - DMAxSA → T_SourceAdd
  - DMAxDA → T_DestAdd

- **DMADTx = 4**
  - AND DMAxSZ = 0 AND DMAEN = 1
Block Transfers

In block transfer mode, a transfer of a complete block of data occurs after one trigger. When DMADTx = 1, the DMAEN bit is cleared after the completion of the block transfer and must be set again before another block transfer can be triggered. After a block transfer has been triggered, further trigger signals occurring during the block transfer are ignored. The block transfer state diagram is shown in Figure 8–4.

The DMAxSZ register is used to define the size of the block and the DMADSTINCRx and DMASRCINCRx bits select if the destination address and the source address are incremented or decremented after each transfer of the block. If DMAxSZ = 0, no transfers occur.

The DMAxSA, DMAxDA, and DMAxSZ registers are copied into temporary registers. The temporary values of DMAxSA and DMAxDA are incremented or decremented after each transfer in the block. The DMAxSZ register is decremented after each transfer of the block and shows the number of transfers remaining in the block. When the DMAxSZ register decrements to zero it is reloaded from its temporary register and the corresponding DMAIFG flag is set.

During a block transfer, the CPU is halted until the complete block has been transferred. The block transfer takes 2 x MCLK x DMAxSZ clock cycles to complete. CPU execution resumes with its previous state after the block transfer is complete.

In repeated block transfer mode, the DMAEN bit remains set after completion of the block transfer. The next trigger after the completion of a repeated block transfer triggers another block transfer.

  - DMAxDA → T_DestAdd

- **DMAREQ = 0**
  - T_Size → DMAxSZ
  - DMAxSA → T_SourceAdd
  - DMAxDA → T_DestAdd
Burst-Block Transfers

In burst-block mode, transfers are block transfers with CPU activity interleaved. The CPU executes 2 MCLK cycles after every four byte/word transfers of the block resulting in 20% CPU execution capacity. After the burst-block, CPU execution resumes at 100% capacity and the DMAEN bit is cleared. DMAEN must be set again before another burst-block transfer can be triggered. After a burst-block transfer has been triggered, further trigger signals occurring during the burst-block transfer are ignored. The burst-block transfer state diagram is shown in Figure 8–5.

The DMAxSZ register is used to define the size of the block and the DMADSTINCRx and DMASRCINCRx bits select if the destination address and the source address are incremented or decremented after each transfer of the block. If DMAxSZ = 0, no transfers occur.

The DMAxSA, DMAxDA, and DMAxSZ registers are copied into temporary registers. The temporary values of DMAxSA and DMAxDA are incremented or decremented after each transfer in the block. The DMAxSZ register is decremented after each transfer of the block and shows the number of transfers remaining in the block. When the DMAxSZ register decrements to zero it is reloaded from its temporary register and the corresponding DMAIFG flag is set.

In repeated burst-block mode the DMAEN bit remains set after completion of the burst-block transfer and no further trigger signals are required to initiate another burst-block transfer. Another burst-block transfer begins immediately after completion of a burst-block transfer. In this case, the transfers must be stopped by clearing the DMAEN bit, or by an NMI interrupt when ENNMI is set. In repeated burst-block mode the CPU executes at 20% capacity continuously until the repeated burst-block transfer is stopped.

8.2.3 Initiating DMA Transfers

Each DMA channel is independently configured for its trigger source with the DMAxTSELx bits as described in Table 8–2 and . The DMAxTSELx bits should be modified only when the DMACTLx DMAEN bit is 0. Otherwise, unpredictable DMA triggers may occur.

When selecting the trigger, the trigger must not have already occurred, or the transfer will not take place. For example, if the TACCR2 CCIFG bit is selected as a trigger, and it is already set, no transfer will occur until the next time the TACCR2 CCIFG bit is set.

Edge-Sensitive Triggers

When DMALEVEL = 0, edge-sensitive triggers are used and the rising edge of the trigger signal initiates the transfer. In single-transfer mode, each transfer requires its own trigger. When using block or burst-block modes, only one trigger is required to initiate the block or burst-block transfer.

Level-Sensitive Triggers

When DMALEVEL = 1, level-sensitive triggers are used. For proper operation, level-sensitive triggers can only be used when external trigger DMAE0 is selected as the trigger. DMA transfers are triggered as long as the trigger signal is high and the DMAEN bit remains set.

The trigger signal must remain high for a block or burst-block transfer to complete. If the trigger signal goes low during a block or burst-block transfer, the DMA controller is held in its current state until the trigger goes back high or until the DMA registers are modified by software. If the DMA registers are not modified by software, when the trigger signal goes high again, the transfer resumes from where it was when the trigger signal went low.

When DMALEVEL = 1, transfer modes selected when DMADTx = {0, 1, 2, 3} are recommended because the DMAEN bit is automatically reset after the configured transfer.

Halting Executing Instructions for DMA Transfers

The DMAONFETCH bit controls when the CPU is halted for a DMA transfer. When DMAONFETCH = 0, the CPU is halted immediately and the transfer begins when a trigger is received. When DMAONFETCH = 1, the CPU finishes the currently executing instruction before the DMA controller halts the CPU and the transfer begins.

Note: DMAONFETCH Must Be Used When The DMA Writes To Flash

If the DMA controller is used to write to flash memory, the DMAONFETCH bit must be set. Otherwise, unpredictable operation can result.

</tr>
<tr>
<td>1111</td>
<td>A transfer is triggered by the external trigger DMAE0.</td>
</tr>
</tbody>
</table>
8.2.4 Stopping DMA Transfers

There are two ways to stop DMA transfers in progress:

- A single, block, or burst-block transfer may be stopped with an NMI interrupt, if the ENNMI bit is set in register DMACTL1.
- A burst-block transfer may be stopped by clearing the DMAEN bit.

8.2.5 DMA Channel Priorities

The default DMA channel priorities are DMA0–DMA1–DMA2. If two or three triggers happen simultaneously or are pending, the channel with the highest priority completes its transfer (single, block or burst-block transfer) first, then the second priority channel, then the third priority channel. Transfers in progress are not halted if a higher priority channel is triggered. The higher priority channel waits until the transfer in progress completes before starting.

The DMA channel priorities are configurable with the ROUNDROBIN bit. When the ROUNDROBIN bit is set, the channel that completes a transfer becomes the lowest priority. The order of the priority of the channels always stays the same, DMA0–DMA1–DMA2, for example:

<table>
<thead>
<tr>
<th>DMA Priority</th>
<th>Transfer Occurs</th>
<th>New DMA Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>DMA0 – DMA1 – DMA2</td>
<td>DMA1</td>
<td>DMA2 – DMA0 – DMA1</td>
</tr>
<tr>
<td>DMA2 – DMA0 – DMA1</td>
<td>DMA2</td>
<td>DMA0 – DMA1 – DMA2</td>
</tr>
<tr>
<td>DMA0 – DMA1 – DMA2</td>
<td>DMA0</td>
<td>DMA1 – DMA2 – DMA0</td>
</tr>
</tbody>
</table>

When the ROUNDROBIN bit is cleared the channel priority returns to the default priority.
8.2.6 DMA Transfer Cycle Time

The DMA controller requires one or two MCLK clock cycles to synchronize before each single transfer or complete block or burst-block transfer. Each byte/word transfer requires two MCLK cycles after synchronization, and one cycle of wait time after the transfer. Because the DMA controller uses MCLK, the DMA cycle time is dependent on the MSP430 operating mode and clock system setup.

If the MCLK source is active, but the CPU is off, the DMA controller will use the MCLK source for each transfer, without re-enabling the CPU. If the MCLK source is off, the DMA controller will temporarily restart MCLK, sourced with DCOCLK, for the single transfer or complete block or burst-block transfer. The CPU remains off, and after the transfer completes, MCLK is turned off. The maximum DMA cycle time for all operating modes is shown in Table 8–3.

Table 8–3. Maximum Single-Transfer DMA Cycle Time

<table>
<thead>
<tr>
<th>CPU Operating Mode</th>
<th>Clock Source</th>
<th>Maximum DMA Cycle Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active mode</td>
<td>MCLK=DCOCLK</td>
<td>4 MCLK cycles</td>
</tr>
<tr>
<td>Active mode</td>
<td>MCLK=LFXT1CLK</td>
<td>4 MCLK cycles</td>
</tr>
<tr>
<td>Low-power mode LPM0/1</td>
<td>MCLK=DCOCLK</td>
<td>5 MCLK cycles</td>
</tr>
<tr>
<td>Low-power mode LPM3/4</td>
<td>MCLK=DCOCLK</td>
<td>5 MCLK cycles + 6 µs†</td>
</tr>
<tr>
<td>Low-power mode LPM0/1</td>
<td>MCLK=LFXT1CLK</td>
<td>5 MCLK cycles</td>
</tr>
<tr>
<td>Low-power mode LPM3</td>
<td>MCLK=LFXT1CLK</td>
<td>5 MCLK cycles</td>
</tr>
<tr>
<td>Low-power mode LPM4</td>
<td>MCLK=LFXT1CLK</td>
<td>5 MCLK cycles + 6 µs†</td>
</tr>
</tbody>
</table>

† The additional 6 µs are needed to start the DCOCLK. It is the \( t_{LPMx} \) parameter in the data sheet.
8.2.7 Using DMA with System Interrupts

DMA transfers are not interruptible by system interrupts. System interrupts remain pending until the completion of the transfer. NMI interrupts can interrupt the DMA controller if the ENNMI bit is set.

System interrupt service routines are interrupted by DMA transfers. If an interrupt service routine or other routine must execute with no interruptions, the DMA controller should be disabled prior to executing the routine.

8.2.8 DMA Controller Interrupts

Each DMA channel has its own DMAIFG flag. Each DMAIFG flag is set in any mode, when the corresponding DMAxSZ register counts to zero. If the corresponding DMAIE and GIE bits are set, an interrupt request is generated.

All DMAIFG flags source only one DMA controller interrupt vector and the interrupt vector is shared with the DAC12 module. Software must check the DMAIFG and DAC12IFG flags to determine the source of the interrupt. The DMAIFG flags are not reset automatically and must be reset by software.
8.2.9 Using the I²C Module with the DMA Controller

The I²C module provides two trigger sources for the DMA controller. The I²C module can trigger a transfer when new I²C data is received and when the transmit data is needed.

The TXDMAEN and RXDMAEN bits enable or disable the use of the DMA controller with the I²C module. When RXDMAEN = 1, the DMA controller can be used to transfer data from the I²C module after the I²C module receives data. When RXDMAEN = 1, RXRDYIE is ignored and RXRDYIFG will not generate an interrupt.

When TXDMAEN = 1, the DMA controller can be used to transfer data to the I²C module for transmission. When TXDMAEN = 1, TXRDYIE is ignored and TXRDYIFG will not generate an interrupt.

8.2.10 Using ADC12 with the DMA Controller

MSP430 devices with an integrated DMA controller can automatically move data from any ADC12MEMx register to another location. DMA transfers are done without CPU intervention and independently of any low-power modes. The DMA controller increases throughput of the ADC12 module, and enhances low-power applications allowing the CPU to remain off while data transfers occur.

DMA transfers can be triggered from any ADC12IFGx flag. When CONSEQx = \{0,2\} the ADC12IFGx flag for the ADC12MEMx used for the conversion can trigger a DMA transfer. When CONSEQx = \{1,3\}, the ADC12IFGx flag for the last ADC12MEMx in the sequence can trigger a DMA transfer. Any ADC12IFGx flag is automatically cleared when the DMA controller accesses the corresponding ADC12MEMx.

8.2.11 Using DAC12 With the DMA Controller

MSP430 devices with an integrated DMA controller can automatically move data to the DAC12_xDAT register. DMA transfers are done without CPU intervention and independently of any low-power modes. The DMA controller increases throughput to the DAC12 module, and enhances low-power applications allowing the CPU to remain off while data transfers occur.

Applications requiring periodic waveform generation can benefit from using the DMA controller with the DAC12. For example, an application that produces a sinusoidal waveform may store the sinusoid values in a table. The DMA controller can continuously and automatically transfer the values to the DAC12 at specific intervals creating the sinusoid with zero CPU execution. The DAC12_xCTL DAC12IFG flag is automatically cleared when the DMA controller accesses the DAC12_xDAT register.
### 8.3 DMA Registers

**Reserved** Bit 15 Reserved

**DMADTx** Bits 14–12
- 000 Single transfer
- 001 Block transfer
- 010 Burst-block transfer
- 011 Burst-block transfer
- 100 Repeated single transfer
- 101 Repeated block transfer
- 110 Repeated burst-block transfer
- 111 Repeated burst-block transfer

**DMA DSTINCRx** Bits 11–10
- DMA destination increment. This bit selects automatic incrementing or decrementing of the destination address after each byte or word transfer. When DMADSTBYTE=1, the destination address increments/decrements by one. When DMADSTBYTE=0, the destination address increments/decrements by two. The DMAxDA is copied into a temporary register and the temporary register is incremented or decremented. DMAxDA is not incremented or decremented.
  - 00 Destination address is unchanged
  - 01 Destination address is unchanged
  - 10 Destination address is decremented
  - 11 Destination address is incremented

**DMASRCINCRx** Bits 9–8
- DMA source increment. This bit selects automatic incrementing or decrementing of the source address for each byte or word transfer. When DMASRCBYTE=1, the source address increments/decrements by one. When DMASRCBYTE=0, the source address increments/decrements by two. The DMAxSA is copied into a temporary register and the temporary register is incremented or decremented. DMAxSA is not incremented or decremented.
  - 00 Source address is unchanged
  - 01 Source address is unchanged
  - 10 Source address is decremented
  - 11 Source address is incremented

**DMA DSTBYTE** Bit 7
- DMA destination byte. This bit selects the destination as a byte or word.
  - 0 Word
  - 1 Byte
**DMA SRCBYTE** Bit 6 DMA source byte. This bit selects the source as a byte or word.
- 0 Word
- 1 Byte

**DMA LEVEL** Bit 5 DMA level. This bit selects between edge-sensitive and level-sensitive triggers.
- 0 Edge sensitive (rising edge)
- 1 Level sensitive (high level)

**DMAEN** Bit 4 DMA enable
- 0 Disabled
- 1 Enabled

**DMAIFG** Bit 3 DMA interrupt flag
- 0 No interrupt pending
- 1 Interrupt pending

**DMAIE** Bit 2 DMA interrupt enable
- 0 Disabled
- 1 Enabled

**DMA ABORT** Bit 1 DMA Abort. This bit indicates if a DMA transfer was interrupt by an NMI.
- 0 DMA transfer not interrupted
- 1 DMA transfer was interrupted by NMI

**DMAREQ** Bit 0 DMA request. Software-controlled DMA start. DMAREQ is reset automatically.
- 0 No DMA start
- 1 Start DMA

</tr>
</tbody>
</table>
9.1 Digital I/O Introduction

MSP430 devices have up to 6 digital I/O ports implemented, P1 - P6. Each port has eight I/O pins. Every I/O pin is individually configurable for input or output direction, and each I/O line can be individually read or written to.

Ports P1 and P2 have interrupt capability. Each interrupt for the P1 and P2 I/O lines can be individually enabled and configured to provide an interrupt on a rising edge or falling edge of an input signal. All P1 I/O lines source a single interrupt vector, and all P2 I/O lines source a different, single interrupt vector.

The digital I/O features include:

- Independently programmable individual I/Os
- Any combination of input or output
- Individually configurable P1 and P2 interrupts
- Independent input and output data registers
9.2 Digital I/O Operation

The digital I/O is configured with user software. The setup and operation of the digital I/O is discussed in the following sections.

9.2.1 Input Register PxIN

Each bit in each PxIN register reflects the value of the input signal at the corresponding I/O pin when the pin is configured as I/O function.

- Bit = 0: The input is low
- Bit = 1: The input is high

**Note: Writing to Read-Only Registers PxIN**

Writing to these read-only registers results in increased current consumption while the write attempt is active.

9.2.2 Output Registers PxOUT

Each bit in each PxOUT register is the value to be output on the corresponding I/O pin when the pin is configured as I/O function and output direction.

- Bit = 0: The output is low
- Bit = 1: The output is high

9.2.3 Direction Registers PxDIR

Each bit in each PxDIR register selects the direction of the corresponding I/O pin, regardless of the selected function for the pin. PxDIR bits for I/O pins that are selected for other module functions must be set as required by the other function.

- Bit = 0: The port pin is switched to input direction
- Bit = 1: The port pin is switched to output direction
9.2.4 Function Select Registers PxSEL

Port pins are often multiplexed with other peripheral module functions. See the device-specific data sheet to determine pin functions. Each PxSEL bit is used to select the pin function – I/O port or peripheral module function.

Bit = 0: I/O Function is selected for the pin

Bit = 1: Peripheral module function is selected for the pin

Setting PxSELx = 1 does not automatically set the pin direction. Other peripheral module functions may require the PxDIRx bits to be configured according to the direction needed for the module function. See the pin schematics in the device-specific datasheet.

; Output ACLK on P2.0 on MSP430F11x1
   BIS.B #01h,&P2SEL ; Select ACLK function for pin
   BIS.B #01h,&P2DIR ; Set direction to output *Required*

---

**Note:** P1 and P2 Interrupts Are Disabled When PxSEL = 1

When any P1SELx or P2SELx bit is set, the corresponding pin’s interrupt function is disabled. Therefore, signals on these pins will not generate P1 or P2 interrupts, regardless of the state of the corresponding P1IE or P2IE bit.

When a port pin is selected as an input to a peripheral, the input signal to the peripheral is a latched representation of the signal at the device pin. While PxSELx=1, the internal input signal follows the signal at the pin. However, if the PxSELx=0, the input to the peripheral maintains the value of the input signal at the device pin before the PxSELx bit was reset.
9.2.5 P1 and P2 Interrupts

Each pin in ports P1 and P2 have interrupt capability, configured with the PxIFG, PxIE, and PxIES registers. All P1 pins source a single interrupt vector, and all P2 pins source a different single interrupt vector. The PxIFG register can be tested to determine the source of a P1 or P2 interrupt.

Interrupt Flag Registers P1IFG, P2IFG

Each PxIFGx bit is the interrupt flag for its corresponding I/O pin and is set when the selected input signal edge occurs at the pin. All PxIFGx interrupt flags request an interrupt when their corresponding PxIE bit and the GIE bit are set. Each PxIFG flag must be reset with software. Software can also set each PxIFG flag, providing a way to generate a software initiated interrupt.

- Bit = 0: No interrupt is pending
- Bit = 1: An interrupt is pending

Only transitions, not static levels, cause interrupts. If any PxIFGx flag becomes set during a Px interrupt service routine, or is set after the RETI instruction of a Px interrupt service routine is executed, the set PxIFGx flag generates another interrupt. This ensures that each transition is acknowledged.

**Note: PxIFG Flags When Changing PxOUT or PxDIR**

Writing to P1OUT, P1DIR, P2OUT, or P2DIR can result in setting the corresponding P1IFG or P2IFG flags.

**Note: Length of I/O Pin Interrupt Event**

Any external interrupt event should be at least 1.5 times MCLK or longer, to ensure that it is accepted and the corresponding interrupt flag is set.
Interrupt Edge Select Registers P1IES, P2IES

Each PxIES bit selects the interrupt edge for the corresponding I/O pin.

- Bit = 0: The PxIFGx flag is set with a low-to-high transition
- Bit = 1: The PxIFGx flag is set with a high-to-low transition

**Note: Writing to PxIESx**

Writing to P1IES, or P2IES can result in setting the corresponding interrupt flags.

<table>
<thead>
<tr>
<th>PxIESx</th>
<th>PxINx</th>
<th>PxIFGx</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 → 1</td>
<td>0</td>
<td>Unchanged</td>

</tr>
<tr>
<td>1 → 0</td>
<td>0</td>
<td>May be set</td>
</tr>
<tr>
<td>1 → 0</td>
<td>1</td>
<td>Unchanged</td>
</tr>
</tbody>
</table>

Interrupt Enable P1IE, P2IE

Each PxIE bit enables the associated PxIFG interrupt flag.

- Bit = 0: The interrupt is disabled
- Bit = 1: The interrupt is enabled

9.2.6 Configuring Unused Port Pins

Unused I/O pins should be configured as I/O function, output direction, and left unconnected on the PC board, to reduce power consumption. The value of the PxOUT bit is don’t care, since the pin is unconnected. See chapter *System Resets, Interrupts, and Operating Modes* for termination unused pins.
9.3 Digital I/O Registers

Seven registers are used to configure P1 and P2. Four registers are used to configure ports P3 - P6. The digital I/O registers are listed in Table 9–1.

The watchdog timer is a 16-bit timer that can be used as a watchdog or as an interval timer. This chapter describes the watchdog timer. The watchdog timer is implemented in all MSP430x1xx devices.

10.1 Watchdog Timer Introduction

The primary function of the watchdog timer (WDT) module is to perform a controlled system restart after a software problem occurs. If the selected time interval expires, a system reset is generated. If the watchdog function is not needed in an application, the module can be configured as an interval timer and can generate interrupts at selected time intervals.

Features of the watchdog timer module include:

- Four software-selectable time intervals
- Watchdog mode
- Interval mode
- Access to WDT control register is password protected
- Control of RST/NMI pin function
- Selectable clock source
- Can be stopped to conserve power

The WDT block diagram is shown in Figure 9–1.

**Note: Watchdog Timer Powers Up Active**

After a PUC, the WDT module is automatically configured in the watchdog mode with an initial ~32-ms reset interval using the DCOCLK. The user must setup or halt the WDT prior to the expiration of the initial reset interval.
Figure 10–1. Watchdog Timer Block Diagram
10.2 Watchdog Timer Operation

The WDT module can be configured as either a watchdog or interval timer with the WDTCTL register. The WDTCTL register also contains control bits to configure the RST/NMI pin. WDTCTL is a 16-bit, password-protected, read/write register. Any read or write access must use word instructions and write accesses must include the write password 05Ah in the upper byte. Any write to WDTCTL with any value other than 05Ah in the upper byte is a security key violation and triggers a PUC system reset regardless of timer mode. Any read of WDTCTL reads 069h in the upper byte.

10.2.1 Watchdog Timer Counter

The watchdog timer counter (WDTCNT) is a 16-bit up-counter that is not directly accessible by software. The WDTCNT is controlled and time intervals selected through the watchdog timer control register WDTCTL.

The WDTCNT can be sourced from ACLK or SMCLK. The clock source is selected with the WDTSSSEL bit.

10.2.2 Watchdog Mode

After a PUC condition, the WDT module is configured in the watchdog mode with an initial ~32-ms reset interval using the DCOCLK. The user must setup, halt, or clear the WDT prior to the expiration of the initial reset interval or another PUC will be generated. When the WDT is configured to operate in watchdog mode, either writing to WDTCTL with an incorrect password, or expiration of the selected time interval triggers a PUC. A PUC resets the WDT to its default condition and configures the RST/NMI pin to reset mode.

10.2.3 Interval Timer Mode

Setting the WDTTMSEL bit to 1 selects the interval timer mode. This mode can be used to provide periodic interrupts. In interval timer mode, the WDTIFG flag is set at the expiration of the selected time interval. A PUC is not generated in interval timer mode at expiration of the selected timer interval and the WDTIFG enable bit WDTIE remains unchanged.

When the WDTIE bit and the GIE bit are set, the WDTIFG flag requests an interrupt. The WDTIFG interrupt flag is automatically reset when its interrupt request is serviced, or may be reset by software. The interrupt vector address in interval timer mode is different from that in watchdog mode.

---

**Note: Modifying the Watchdog Timer**

The WDT interval should be changed together with WDTCNTCL = 1 in a single instruction to avoid an unexpected immediate PUC or interrupt.

The WDT should be halted before changing the clock source to avoid a possible incorrect interval.
10.2.4 Watchdog Timer Interrupts

The WDT uses two bits in the SFRs for interrupt control.

- The WDT interrupt flag, WDTIFG, located in IFG1.0
- The WDT interrupt enable, WDTIE, located in IE1.0

When using the WDT in the watchdog mode, the WDTIFG flag sources a reset vector interrupt. The WDTIFG can be used by the reset interrupt service routine to determine if the watchdog caused the device to reset. If the flag is set, then the watchdog timer initiated the reset condition either by timing out or by a security key violation. If WDTIFG is cleared, the reset was caused by a different source.

When using the WDT in interval timer mode, the WDTIFG flag is set after the selected time interval and requests a WDT interval timer interrupt if the WDTIE and the GIE bits are set. The interval timer interrupt vector is different from the reset vector used in watchdog mode. In interval timer mode, the WDTIFG flag is reset automatically when the interrupt is serviced, or can be reset with software.
10.2.5 Operation in Low-Power Modes

The MSP430 devices have several low-power modes. Different clock signals are available in different low-power modes. The requirements of the user’s application and the type of clocking used determine how the WDT should be configured. For example, the WDT should not be configured in watchdog mode with SMCLK as its clock source if the user wants to use low-power mode 3 because SMCLK is not active in LPM3 and the WDT would not function. When the watchdog timer is not required, the WDTHOLD bit can be used to hold the WDTCNT, reducing power consumption.

10.2.6 Software Examples

Any write operation to WDTCTL must be a word operation with 05Ah (WDTPW) in the upper byte:

; Periodically clear an active watchdog
   MOV #WDTPW+WDTCNTCL,&WDTCTL
;
; Change watchdog timer interval
   MOV #WDTPW+WDTCNTL+SSEL,&WDTCTL
;
; Stop the watchdog
   MOV #WDTPW+WDTHOLD,&WDTCTL
;
; Change WDT to interval timer mode, clock/8192 interval
   MOV #WDTPW+WDTCNTCL+WDTTMSEL+WDTIS0,&WDTCTL
10.3 Watchdog Timer Registers

The watchdog timer module registers are listed in Table 10–1.

<td></td>
</tr>
</tbody>
</table>

Bit 15-8: WDTPW
- **Watchdog timer password.** Always read as 069h. Must be written as 05Ah, or a PUC will be generated.

Bit 7: WDTHOLD
- **Watchdog timer hold.** This bit stops the watchdog timer. Setting WDTHOLD = 1 when the WDT is not in use conserves power.
  - 0: Watchdog timer is not stopped
  - 1: Watchdog timer is stopped

Bit 6: WDTNMIES
- **Watchdog timer NMI edge select.** This bit selects the interrupt edge for the NMI interrupt when WDTNMI = 1. Modifying this bit can trigger an NMI. Modify this bit when WDTNMI = 0 to avoid triggering an accidental NMI.
  - 0: NMI on rising edge
  - 1: NMI on falling edge

Bit 5: WDTNMI
- **Watchdog timer NMI select.** This bit selects the function for the RST/NMI pin.
  - 0: Reset function
  - 1: NMI function

Bit 4: WDTTMSEL
- **Watchdog timer mode select**
  - 0: Watchdog mode
  - 1: Interval timer mode

Bit 3: WDTCNTCL
- **Watchdog timer counter clear.** Setting WDTCNTCL = 1 clears the count value to 0000h. WDTCNTCL is automatically reset.
  - 0: No action
  - 1: WDTCNT = 0000h

Bit 2: WDTSEL
- **Watchdog timer clock source select**
  - 0: SMCLK
  - 1: ACLK

Bits 1-0: WDTISx
- **Watchdog timer interval select.** These bits select the watchdog timer interval to set the WDTIFG flag and/or generate a PUC.
  - 00: Watchdog clock source /32768
  - 01: Watchdog clock source /8192
  - 10: Watchdog clock source /512
  - 11: Watchdog clock source /64

<td>11-19</td>
</tr>
</tbody>
</table>
11.1 Timer_A Introduction

Timer_A is a 16-bit timer/counter with three capture/compare registers. Timer_A can support multiple capture/compares, PWM outputs, and interval timing. Timer_A also has extensive interrupt capabilities. Interrupts may be generated from the counter on overflow conditions and from each of the capture/compare registers.

Timer_A features include:

- Asynchronous 16-bit timer/counter with four operating modes
- Selectable and configurable clock source
- Three configurable capture/compare registers
- Configurable outputs with PWM capability
- Asynchronous input and output latching
- Interrupt vector register for fast decoding of all Timer_A interrupts

The block diagram of Timer_A is shown in Figure 11–1.

---

**Note: Use of the Word Count**

*Count* is used throughout this chapter. It means the counter must be in the process of counting for the action to take place. If a particular value is directly written to the counter, then an associated action will not take place.
Figure 11–1. Timer_A Block Diagram
11.2 Timer_A Operation

The Timer_A module is configured with user software. The setup and operation of Timer_A is discussed in the following sections.

11.2.1 16-Bit Timer Counter

The 16-bit timer/counter register, TAR, increments or decrements (depending on mode of operation) with each rising edge of the clock signal. TAR can be read or written with software. Additionally, the timer can generate an interrupt when it overflows.

TAR may be cleared by setting the TACLR bit. Setting TACLR also clears the clock divider and count direction for up/down mode.

---

Note: Modifying Timer_A Registers

It is recommended to stop the timer before modifying its operation (with exception of the interrupt enable and interrupt flag) to avoid errant operating conditions.

When the TACLK is asynchronous to the CPU clock, any read from TAR should occur while the timer is not operating or the results may be unpredictable. Any write to TAR will take effect immediately.

---

Clock Source Select and Divider

The timer clock TACLK can be sourced from ACLK, SMCLK, or externally via TACLK or INCLK. The clock source is selected with the TASSELx bits. The selected clock source may be passed directly to the timer or divided by 2, 4, or 8, using the IDx bits. The TACLK divider is reset when TACLR is set.
11.2.2 Starting the Timer

The timer may be started, or restarted in the following ways:

- The timer counts when MCx > 0 and the clock source is active.

- When the timer mode is either up or up/down, the timer may be stopped by writing 0 to TACCR0. The timer may then be restarted by writing a nonzero value to TACCR0. In this scenario, the timer starts incrementing in the up direction from zero.

11.2.3 Timer Mode Control

The timer has four modes of operation as described in Table 11–1: stop, up, continuous, and up/down. The operating mode is selected with the MCx bits.

Table 11–1. Timer Modes

<table>
<thead>
<tr>
<th>MCx</th>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Stop</td>
<td>The timer is halted.</td>
</tr>
<tr>
<td>01</td>

<td>The timer repeatedly counts from zero to 0FFFH.</td>
</tr>
<tr>
<td>11</td>
<td>Up/down</td>
<td>The timer repeatedly counts from zero up to the value of TACCR0 and back down to zero.</td>
</tr>
</tbody>
</table>
**Timer_A Operation**

**Up Mode**

The up mode is used if the timer period must be different from 0xFFFFh counts. The timer repeatedly counts up to the value of compare register TACCR0, which defines the period, as shown in Figure 11–2. The number of timer counts in the period is TACCR0+1. When the timer value equals TACCR0, the timer restarts counting from zero. If up mode is selected when the timer value is greater than TACCR0, the timer immediately restarts counting from zero.

*Figure 11–2. Up Mode*

![Up Mode Diagram](image)

The TACCR0 CCIFG interrupt flag is set when the timer *counts* to the TACCR0 value. The TAIFG interrupt flag is set when the timer *counts* from TACCR0 to zero. Figure 11–3 shows the flag set cycle.

*Figure 11–3. Up Mode Flag Setting*

![Flag Setting Diagram](image)

**Changing the Period Register TACCR0**

When changing TACCR0 while the timer is running, if the new period is greater than or equal to the old period, or greater than the current count value, the timer counts up to the new period. If the new period is less than the current count value, the timer rolls to zero. However, one additional count may occur before the counter rolls to zero.
Continuous Mode

In the continuous mode, the timer repeatedly counts up to 0xFFFFh and restarts from zero as shown in Figure 11–4. The capture/compare register TACCR0 works the same way as the other capture/compare registers.

**Figure 11–4. Continuous Mode**

![Diagram of Continuous Mode](image)

The TAIFG interrupt flag is set when the timer counts from 0xFFFFh to zero. Figure 11–5 shows the flag set cycle.

**Figure 11–5. Continuous Mode Flag Setting**

![Diagram of Continuous Mode Flag Setting](image)
Timer_A Operation

**Use of the Continuous Mode**

The continuous mode can be used to generate independent time intervals and output frequencies. Each time an interval is completed, an interrupt is generated. The next time interval is added to the TACCRx register in the interrupt service routine. Figure 11–6 shows two separate time intervals $t_0$ and $t_1$ being added to the capture/compare registers. In this usage, the time interval is controlled by hardware, not software, without impact from interrupt latency. Up to three independent time intervals or output frequencies can be generated using all three capture/compare registers.

*Figure 11–6. Continuous Mode Time Intervals*

Time intervals can be produced with other modes as well, where TACCR0 is used as the period register. Their handling is more complex since the sum of the old TACCRx data and the new period can be higher than the TACCR0 value. When the previous TACCRx value plus $t_x$ is greater than the TACCR0 data, the TACCR0 value must be subtracted to obtain the correct time interval.
Up/Down Mode

The up/down mode is used if the timer period must be different from 0FFFFh counts, and if symmetrical pulse generation is needed. The timer repeatedly counts up to the value of compare register TACCR0 and back down to zero, as shown in Figure 11–7. The period is twice the value in TACCR0.

Figure 11–7. Up/Down Mode

The count direction is latched. This allows the timer to be stopped and then restarted in the same direction it was counting before it was stopped. If this is not desired, the TACLR bit must be set to clear the direction. The TACLR bit also clears the TAR value and the TACLK divider.

In up/down mode, the TACCR0 CCIFG interrupt flag and the TAIFG interrupt flag are set only once during a period, separated by 1/2 the timer period. The TACCR0 CCIFG interrupt flag is set when the timer counts from TACCR0 – 1 to TACCR0, and TAIFG is set when the timer completes counting down from 0001h to 0000h. Figure 11–8 shows the flag set cycle.

Figure 11–8. Up/Down Mode Flag Setting
*Timer_A Operation*

**Changing the Period Register TACCR0**

When changing TACCR0 while the timer is running, and counting in the down direction, the timer continues its descent until it reaches zero. The new period takes affect after the counter counts down to zero.

When the timer is counting in the up direction, and the new period is greater than or equal to the old period, or greater than the current count value, the timer counts up to the new period before counting down. When the timer is counting in the up direction, and the new period is less than the current count value, the timer begins counting down. However, one additional count may occur before the counter begins counting down.

**Use of the Up/Down Mode**

The up/down mode supports applications that require dead times between output signals (See section *Timer_A Output Unit*). For example, to avoid overload conditions, two outputs driving an H-bridge must never be in a high state simultaneously. In the example shown in Figure 11–9 the $t_{\text{dead}}$ is:

$$t_{\text{dead}} = t_{\text{timer}} \times (\text{TACCR1} - \text{TACCR2})$$

With:
- $t_{\text{dead}}$: Time during which both outputs need to be inactive
- $t_{\text{timer}}$: Cycle time of the timer clock
- TACCRx: Content of capture/compare register x

The TACCRx registers are not buffered. They update immediately when written to. Therefore, any required dead time will not be maintained automatically.

*Figure 11–9. Output Unit in Up/Down Mode*
11.2.4 Capture/Compare Blocks

Three identical capture/compare blocks, TACCRx, are present in Timer_A. Any of the blocks may be used to capture the timer data, or to generate time intervals.

Capture Mode

The capture mode is selected when CAP = 1. Capture mode is used to record time events. It can be used for speed computations or time measurements. The capture inputs CClxA and CClxB are connected to external pins or internal signals and are selected with the CCISx bits. The CMx bits select the capture edge of the input signal as rising, falling, or both. A capture occurs on the selected edge of the input signal. If a capture occurs:

- The timer value is copied into the TACCRx register
- The interrupt flag CCIFG is set

The input signal level can be read at any time via the CCI bit. MSP430x1xx family devices may have different signals connected to CClxA and CClxB. Refer to the device-specific datasheet for the connections of these signals.

The capture signal can be asynchronous to the timer clock and cause a race condition. Setting the SCS bit will synchronize the capture with the next timer clock. Setting the SCS bit to synchronize the capture signal with the timer clock is recommended. This is illustrated in Figure 11-10.

*Figure 11-10. Capture Signal (SCS=1)*

Overflow logic is provided in each capture/compare register to indicate if a second capture was performed before the value from the first capture was read. Bit COV is set when this occurs as shown in Figure 11-11. COV must be reset with software.
Capture Initiated by Software

Captures can be initiated by software. The CMx bits can be set for capture on both edges. Software then sets CCI = 1 and toggles bit CCIS0 to switch the capture signal between $V_{CC}$ and GND, initiating a capture each time CCIS0 changes state:

\[
\text{MOV} \ #\text{CAP+SCS+CCIS1+CM_3,}\&\text{TACCTLx}; \ \text{Setup TACCTLx} \\
\text{XOR} \ #\text{CCIS0,}\&\text{TACCTLx}; \ \text{TACCTLx} = \text{TAR}
\]

Compare Mode

The compare mode is selected when CAP = 0. The compare mode is used to generate PWM output signals or interrupts at specific time intervals. When TAR counts to the value in a TACCRx:

- Interrupt flag CCIFG is set
- Internal signal EQUx = 1
- EQUx affects the output according to the output mode
- The input signal CCI is latched into SCCI
11.2.5 Output Unit

Each capture/compare block contains an output unit. The output unit is used to generate output signals such as PWM signals. Each output unit has eight operating modes that generate signals based on the EQU0 and EQUx signals.

Output Modes

The output modes are defined by the OUTMODx bits and are described in Table 11–2. The OUTx signal is changed with the rising edge of the timer clock for all modes except mode 0. Output modes 2, 3, 6, and 7 are not useful for output unit 0 because EQUx = EQU0.

Output Example—Timer in Up Mode

The OUTx signal is changed when the timer counts up to the TACCRx value, and rolls from TACCR0 to zero, depending on the output mode. An example is shown in Figure 11–12 using TACCR0 and TACCR1.

Figure 11–12. Output Example—Timer in Up Mode
Output Example—Timer in Continuous Mode

The OUTx signal is changed when the timer reaches the TACCRx and TACCR0 values, depending on the output mode. An example is shown in Figure 11–13 using TACCR0 and TACCR1.

Figure 11–13. Output Example—Timer in Continuous Mode
**Output Example—Timer in Up/Down Mode**

The OUTx signal changes when the timer equals TACCRx in either count direction and when the timer equals TACCR0, depending on the output mode. An example is shown in Figure 11–14 using TACCR0 and TACCR2.

**Figure 11–14. Output Example—Timer in Up/Down Mode**

Note: **Switching Between Output Modes**

When switching between output modes, one of the OUTMODx bits should remain set during the transition, unless switching to mode 0. Otherwise, output glitching can occur because a NOR gate decodes output mode 0. A safe method for switching between output modes is to use output mode 7 as a transition state:

```
BIS #OUTMOD_7, &TACCTLx ; Set output mode=7
BIC #OUTMODx, &TACCTLx ; Clear unwanted bits
```
11.2.6 Timer_A Interrupts

Two interrupt vectors are associated with the 16-bit Timer_A module:

- TACCR0 interrupt vector for TACCR0 CCIFG
- TAIV interrupt vector for all other CCIFG flags and TAIFG

In capture mode any CCIFG flag is set when a timer value is captured in the associated TACCRx register. In compare mode, any CCIFG flag is set if TAR counts to the associated TACCRx value. Software may also set or clear any CCIFG flag. All CCIFG flags request an interrupt when their corresponding CCIE bit and the GIE bit are set.

**TACCR0 Interrupt**

The TACCR0 CCIFG flag has the highest Timer_A interrupt priority and has a dedicated interrupt vector as shown in Figure 11–15. The TACCR0 CCIFG flag is automatically reset when the TACCR0 interrupt request is serviced.

Figure 11–15.Capture/Compare TACCR0 Interrupt Flag

**TAIV, Interrupt Vector Generator**

The TACCR1 CCIFG, TACCR2 CCIFG, and TAIFG flags are prioritized and combined to source a single interrupt vector. The interrupt vector register TAIV is used to determine which flag requested an interrupt.

The highest priority enabled interrupt generates a number in the TAIV register (see register description). This number can be evaluated or added to the program counter to automatically enter the appropriate software routine. Disabled Timer_A interrupts do not affect the TAIV value.

Any access, read or write, of the TAIV register automatically resets the highest pending interrupt flag. If another interrupt flag is set, another interrupt is immediately generated after servicing the initial interrupt. For example, if the TACCR1 and TACCR2 CCIFG flags are set when the interrupt service routine accesses the TAIV register, TACCR1 CCIFG is reset automatically. After the RETI instruction of the interrupt service routine is executed, the TACCR2 CCIFG flag will generate another interrupt.
**TAIV Software Example**

The following software example shows the recommended use of TAIV and the handling overhead. The TAIV value is added to the PC to automatically jump to the appropriate routine.

The numbers at the right margin show the necessary CPU cycles for each instruction. The software overhead for different interrupt sources includes interrupt latency and return-from-interrupt cycles, but not the task handling itself. The latencies are:

- Capture/compare block TACCR0: 11 cycles
- Capture/compare blocks TACCR1, TACCR2: 16 cycles
- Timer overflow TAIFG: 14 cycles

```assembly

Timer_B is a 16-bit timer/counter with multiple capture/compare registers. This chapter describes Timer_B. Timer_B3 (three capture/compare registers) is implemented in MSP430x13x and MSP430x15x devices. Timer_B7 (seven capture/compare registers) is implemented in MSP430x14x and MSP430x16x devices.

</tr>
</tbody>
</table>
12.1 Timer_B Introduction

Timer_B is a 16-bit timer/counter with three or seven capture/compare registers. Timer_B can support multiple capture/compares, PWM outputs, and interval timing. Timer_B also has extensive interrupt capabilities. Interrupts may be generated from the counter on overflow conditions and from each of the capture/compare registers.

Timer_B features include:

- Asynchronous 16-bit timer/counter with four operating modes and four selectable lengths
- Selectable and configurable clock source
- Three or seven configurable capture/compare registers
- Configurable outputs with PWM capability
- Double-buffered compare latches with synchronized loading
- Interrupt vector register for fast decoding of all Timer_B interrupts

The block diagram of Timer_B is shown in Figure 12–1.

Note: Use of the Word Count

Count is used throughout this chapter. It means the counter must be in the process of counting for the action to take place. If a particular value is directly written to the counter, then an associated action does not take place.

12.1.1 Similarities and Differences From Timer_A

Timer_B is identical to Timer_A with the following exceptions:

- The length of Timer_B is programmable to be 8, 10, 12, or 16 bits.
- Timer_B TBCCRx registers are double-buffered and can be grouped.
- All Timer_B outputs can be put into a high-impedance state.
- The SCCI bit function is not implemented in Timer_B.
Figure 12–1. Timer_B Block Diagram
12.2 Timer_B Operation

The Timer_B module is configured with user software. The setup and operation of Timer_B is discussed in the following sections.

12.2.1 16-Bit Timer Counter

The 16-bit timer/counter register, TBR, increments or decrements (depending on mode of operation) with each rising edge of the clock signal. TBR can be read or written with software. Additionally, the timer can generate an interrupt when it overflows.

TBR may be cleared by setting the TBCLR bit. Setting TBCLR also clears the clock divider and count direction for up/down mode.

**Note: Modifying Timer_B Registers**

It is recommended to stop the timer before modifying its operation (with exception of the interrupt enable and interrupt flag) to avoid errant operating conditions.

When TBCLK is asynchronous to the CPU clock, any read from TBR should occur while the timer is not operating or the results may be unpredictable. Any write to TBR will take effect immediately.

**TBR Length**

Timer_B is configurable to operate as an 8-, 10-, 12-, or 16-bit timer with the CNTLx bits. The maximum count value, $TBR_{\text{max}}$, for the selectable lengths is $0\text{FFh}$, $0\text{3FFh}$, $0\text{FFh}$, and $0\text{FFFFh}$, respectively. Data written to the TBR register in 8-, 10-, and 12-bit mode is right-justified with leading zeros.

**Clock Source Select and Divider**

The timer clock TBCLK can be sourced from ACLK, SMCLK, or externally via TBCLK or INCLK. The clock source is selected with the TBSSELx bits. The selected clock source may be passed directly to the timer or divided by 2, 4, or 8, using the IDx bits. The TBCLK divider is reset when TBCLR is set.
12.2.2 Starting the Timer

The timer may be started or restarted in the following ways:

- The timer counts when MCx > 0 and the clock source is active.
- When the timer mode is either up or up/down, the timer may be stopped by loading 0 to TBCL0. The timer may then be restarted by loading a nonzero value to TBCL0. In this scenario, the timer starts incrementing in the up direction from zero.

12.2.3 Timer Mode Control

The timer has four modes of operation as described in Table 12–1: stop, up, continuous, and up/down. The operating mode is selected with the MCx bits.

Table 12–1. Timer Modes

<table>
<thead>
<tr>
<th>MCx</th>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Stop</td>
<td>The timer is halted.</td>
</tr>
<tr>
<td>01</td>
<td>Up</td>
<td>The timer repeatedly counts from zero to the value of compare register TBCL0.</td>
</tr>
<tr>
<td>10</td>
<td>Continuous</td>
<td>The timer repeatedly counts from zero to the value selected by the TBCNTLx bits.</td>
</tr>
<tr>
<td>11</td>
<td>Up/down</td>
<td>The timer repeatedly counts from zero up to the value of TBCL0 and then back down to zero.</td>
</tr>
</tbody>
</table>
Up Mode

The up mode is used if the timer period must be different from \( TBR_{(\text{max})} \) counts. The timer repeatedly counts up to the value of compare latch TBCL0, which defines the period, as shown in Figure 12–2. The number of timer counts in the period is TBCL0+1. When the timer value equals TBCL0 the timer restarts counting from zero. If up mode is selected when the timer value is greater than TBCL0, the timer immediately restarts counting from zero.

**Figure 12–2. Up Mode**

The TBCCR0 CCIFG interrupt flag is set when the timer counts to the TBCL0 value. The TBIFG interrupt flag is set when the timer counts from TBCL0 to zero. Figure 11–3 shows the flag set cycle.

**Figure 12–3. Up Mode Flag Setting**

Changing the Period Register TBCL0

When changing TBCL0 while the timer is running and when the TBCL0 load mode is *immediate*, if the new period is greater than or equal to the old period, or greater than the current count value, the timer counts up to the new period. If the new period is less than the current count value, the timer rolls to zero. However, one additional count may occur before the counter rolls to zero.
Continuous Mode

In continuous mode the timer repeatedly counts up to $TBR_{(\text{max})}$ and restarts from zero as shown in Figure 12–4. The compare latch TBCL0 works the same way as the other capture/compare registers.

*Figure 12–4. Continuous Mode*

![Diagram of Continuous Mode](image)

The TBIFG interrupt flag is set when the timer counts from $TBR_{(\text{max})}$ to zero. Figure 12–5 shows the flag set cycle.

*Figure 12–5. Continuous Mode Flag Setting*
Use of the Continuous Mode

The continuous mode can be used to generate independent time intervals and output frequencies. Each time an interval is completed, an interrupt is generated. The next time interval is added to the TBCLx latch in the interrupt service routine. Figure 12–6 shows two separate time intervals $t_0$ and $t_1$ being added to the capture/compare registers. The time interval is controlled by hardware, not software, without impact from interrupt latency. Up to three (Timer_B3) or 7 (Timer_B7) independent time intervals or output frequencies can be generated using capture/compare registers.

Figure 12–6. Continuous Mode Time Intervals

Time intervals can be produced with other modes as well, where TBCL0 is used as the period register. Their handling is more complex since the sum of the old TBCLx data and the new period can be higher than the TBCL0 value. When the sum of the previous TBCLx value plus $t_x$ is greater than the TBCL0 data, the old TBCL0 value must be subtracted to obtain the correct time interval.
**Up/Down Mode**

The up/down mode is used if the timer period must be different from \( TBR_{(\text{max})} \) counts, and if symmetrical pulse generation is needed. The timer repeatedly counts up to the value of compare latch TBCL0, and back down to zero, as shown in Figure 12–7. The period is twice the value in TBCL0.

**Note:** TBCL0 > TBR\(^{(\text{max})}\)

If TBCL0 > TBR\(^{(\text{max})}\), the counter operates as if it were configured for continuous mode. It does not count down from TBR\(^{(\text{max})}\) to zero.

**Figure 12–7. Up/Down Mode**

The count direction is latched. This allows the timer to be stopped and then restarted in the same direction it was counting before it was stopped. If this is not desired, the TBCLR bit must be used to clear the direction. The TBCLR bit also clears the TBR value and the TBCLK divider.

In up/down mode, the TBCCR0 CCIFG interrupt flag and the TBIFG interrupt flag are set only once during the period, separated by 1/2 the timer period. The TBCCR0 CCIFG interrupt flag is set when the timer counts from TBCL0–1 to TBCL0, and TBIFG is set when the timer completes counting down from 0001h to 0000h. Figure 12–8 shows the flag set cycle.

**Figure 12–8. Up/Down Mode Flag Setting**
Changing the Value of Period Register TBCL0

When changing TBCL0 while the timer is running, and counting in the down direction, and when the TBCL0 load mode is immediate, the timer continues its descent until it reaches zero. The new period takes effect after the counter counts down to zero.

If the timer is counting in the up direction when the new period is latched into TBCL0, and the new period is greater than or equal to the old period, or greater than the current count value, the timer counts up to the new period before counting down. When the timer is counting in the up direction, and the new period is less than the current count value when TBCL0 is loaded, the timer begins counting down. However, one additional count may occur before the counter begins counting down.

Use of the Up/Down Mode

The up/down mode supports applications that require dead times between output signals (see section Timer_B Output Unit). For example, to avoid overload conditions, two outputs driving an H-bridge must never be in a high state simultaneously. In the example shown in Figure 12–9 the \( t_{dead} \) is:

\[
t_{dead} = t_{timer} \times (TBCL1 - TBCL3)
\]

With:
- \( t_{dead} \) Time during which both outputs need to be inactive
- \( t_{timer} \) Cycle time of the timer clock
- \( TBCLx \) Content of compare latch x

The ability to simultaneously load grouped compare latches assures the dead times.

Figure 12–9. Output Unit in Up/Down Mode
12.2.4 Capture/Compare Blocks

Three or seven identical capture/compare blocks, TBCCRx, are present in Timer_B. Any of the blocks may be used to capture the timer data or to generate time intervals.

Capture Mode

The capture mode is selected when CAP = 1. Capture mode is used to record time events. It can be used for speed computations or time measurements. The capture inputs CClxA and CClxB are connected to external pins or internal signals and are selected with the CCISx bits. The CMx bits select the capture edge of the input signal as rising, falling, or both. A capture occurs on the selected edge of the input signal. If a capture is performed:

- The timer value is copied into the TBCCRx register
- The interrupt flag CCIFG is set

The input signal level can be read at any time via the CCI bit. MSP430x1xx family devices may have different signals connected to CClxA and CClxB. Refer to the device-specific datasheet for the connections of these signals.

The capture signal can be asynchronous to the timer clock and cause a race condition. Setting the SCS bit will synchronize the capture with the next timer clock. Setting the SCS bit to synchronize the capture signal with the timer clock is recommended. This is illustrated in Figure 12–10.

Figure 12–10. Capture Signal (SCS=1)

Overflow logic is provided in each capture/compare register to indicate if a second capture was performed before the value from the first capture was read. Bit COV is set when this occurs as shown in Figure 12–11. COV must be reset with software.
Capture Initiated by Software

Captures can be initiated by software. The CMx bits can be set for capture on both edges. Software then sets bit CCIS1=1 and toggles bit CCIS0 to switch the capture signal between VCC and GND, initiating a capture each time CCIS0 changes state:

\[
\text{MOV} \ #\text{CAP+SCS+CCIS1+CM}_3, \&\text{TBCCTLx}; \ \text{Set up TBCCTLx} \\
\text{XOR} \ #\text{CCIS0}, \&\text{TBCCTLx} \ ; \ \text{TBCCTLx} = \text{TBR}
\]

Compare Mode

The compare mode is selected when CAP = 0. Compare mode is used to generate PWM output signals or interrupts at specific time intervals. When TBR counts to the value in a TBCLx:

- Interrupt flag CCIFG is set
- Internal signal EQUx = 1
- EQUx affects the output according to the output mode
**Timer_B Operation**

**Compare Latch TBCLx**

The TBCCRx compare latch, TBCLx, holds the data for the comparison to the timer value in compare mode. TBCLx is buffered by TBCCRx. The buffered compare latch gives the user control over when a compare period updates. The user cannot directly access TBCLx. Compare data is written to each TBCCRx and automatically transferred to TBCLx. The timing of the transfer from TBCCRx to TBCLx is user-selectable with the CLLDx bits as described in Table 12–2.

**Table 12–2. TBCLx Load Events**

<table>
<thead>
<tr>

<tr>
<td>10</td>
<td>New data is transferred from TBCCRx to TBCLx when TBR counts to 0 for up and continuous modes. New data is transferred to from TBCCRx to TBCLx when TBR counts to the old TBCL0 value or to 0 for up/down mode</td>
</tr>
<tr>
<td>11</td>
<td>New data is transferred from TBCCRx to TBCLx when TBR counts to the old TBCLx value.</td>
</tr>
</tbody>
</table>

**Grouping Compare Latches**

Multiple compare latches may be grouped together for simultaneous updates with the TBCLGRPx bits. When using groups, the CLLDx bits of the lowest numbered TBCCRx in the group determine the load event for each compare latch of the group, except when TBCLGRPx = 3, as shown in Table 12–3. The CLLDx bits of the controlling TBCCRx must not be set to zero. When the CLLDx bits of the controlling TBCCRx are set to zero, all compare latches update immediately when their corresponding TBCCRx is written - no compare latches are grouped.

Two conditions must exist for the compare latches to be loaded when grouped. First, all TBCCRx registers of the group must be updated, even when new TBCCRx data = old TBCCRx data. Second, the load event must occur.

12.2.5 Output Unit

Each capture/compare block contains an output unit. The output unit is used to generate output signals such as PWM signals. Each output unit has eight operating modes that generate signals based on the EQU0 and EQUx signals. The TBOUTH pin function can be used to put all Timer B outputs into a high-impedance state. When the TBOUTH pin function is selected for the pin, and when the pin is pulled high, all Timer_B outputs are in a high-impedance state.

Output Modes

The output modes are defined by the OUTMODx bits and are described in Table 12–4. The OUTx signal is changed with the rising edge of the timer clock for all modes except mode 0. Output modes 2, 3, 6, and 7 are not useful for output unit 0 because EQUx = EQU0.

Table 12–4. Output Modes

<table>
<thead>

<td>The output is reset when the timer counts to the TBCLx value. It is set when the timer counts to the TBCL0 value.</td>
</tr>
</tbody>
</table>
Output Example—Timer in Up Mode

The OUTx signal is changed when the timer counts up to the TBCLx value, and rolls from TBCL0 to zero, depending on the output mode. An example is shown in Figure 12–12 using TBCL0 and TBCL1.

Figure 12–12. Output Example—Timer in Up Mode
Output Example—Timer in Continuous Mode

The OUTx signal is changed when the timer reaches the TBCLx and TBCL0 values, depending on the output mode. An example is shown in Figure 12–13 using TBCL0 and TBCL1.

Figure 12–13. Output Example—Timer in Continuous Mode
Output Example – Timer in Up/Down Mode

The OUTx signal changes when the timer equals TBCLx in either count direction and when the timer equals TBCL0, depending on the output mode. An example is shown in Figure 12–14 using TBCL0 and TBCL3.

Figure 12–14. Output Example—Timer in Up/Down Mode

Note: Switching Between Output Modes

When switching between output modes, one of the OUTMODx bits should remain set during the transition, unless switching to mode 0. Otherwise, output glitching can occur because a NOR gate decodes output mode 0. A safe method for switching between output modes is to use output mode 7 as a transition state:

BIS #OUTMOD_7,&TBCCTLx ; Set output mode=7
BIC #OUTMODx,&TBCCTLx ; Clear unwanted bits
12.2.6 Timer_B Interrupts

Two interrupt vectors are associated with the 16-bit Timer_B module:

- TBCCR0 interrupt vector for TBCCR0 CCIFG
- TBIV interrupt vector for all other CCIFG flags and TBIFG

In capture mode, any CCIFG flag is set when a timer value is captured in the associated TBCCRx register. In compare mode, any CCIFG flag is set when TBR counts to the associated TBCLx value. Software may also set or clear any CCIFG flag. All CCIFG flags request an interrupt when their corresponding CCIE bit and the GIE bit are set.

**TBCCR0 Interrupt Vector**

The TBCCR0 CCIFG flag has the highest Timer_B interrupt priority and has a dedicated interrupt vector as shown in Figure 12–15. The TBCCR0 CCIFG flag is automatically reset when the TBCCR0 interrupt request is serviced.

**Figure 12–15. Capture/Compare TBCCR0 Interrupt Flag**

![Figure 12–15. Capture/Compare TBCCR0 Interrupt Flag](image)

**TBIV, Interrupt Vector Generator**

The TBIFG flag and TBCCRx CCIFG flags (excluding TBCCR0 CCIFG) are prioritized and combined to source a single interrupt vector. The interrupt vector register TBIV is used to determine which flag requested an interrupt.

The highest priority enabled interrupt (excluding TBCCR0 CCIFG) generates a number in the TBIV register (see register description). This number can be evaluated or added to the program counter to automatically enter the appropriate software routine. Disabled Timer_B interrupts do not affect the TBIV value.

Any access, read or write, of the TBIV register automatically resets the highest pending interrupt flag. If another interrupt flag is set, another interrupt is immediately generated after servicing the initial interrupt. For example, if the TBCCR1 and TBCCR2 CCIFG flags are set when the interrupt service routine accesses the TBIV register, TBCCR1 CCIFG is reset automatically. After the RETI instruction of the interrupt service routine is executed, the TBCCR2 CCIFG flag will generate another interrupt.
TBIV, Interrupt Handler Examples

The following software example shows the recommended use of TBIV and the handling overhead. The TBIV value is added to the PC to automatically jump to the appropriate routine.

The numbers at the right margin show the necessary CPU clock cycles for each instruction. The software overhead for different interrupt sources includes interrupt latency and return-from-interrupt cycles, but not the task handling itself. The latencies are:

- Capture/compare block CCR0: 11 cycles
- Capture/compare blocks CCR1 to CCR6: 16 cycles
- Timer overflow TBIFG: 14 cycles

The following software example shows the recommended use of TBIV for Timer_B3.

```assembly
; Interrupt handler for TBCCR0 CCIFG. Cycles
CCIFG_0_HND
...                   ; Start of handler Interrupt latency 6
RETI                  5

; Interrupt handler for TBIFG, TBCCR1 and TBCCR2 CCIFG.
TB_HND                ; Interrupt latency 6
ADD &TBIV,PC          ; Add offset to Jump table 3
RETI                  ; Vector 0: No interrupt 5
JMP CCIFG_1_HND       ; Vector 2: Module 1 2
JMP CCIFG_2_HND       ; Vector 4: Module 2 2
RETI                  ; Vector 6
RETI                  ; Vector 8
RETI                  ; Vector 10
RETI                  ; Vector 12

TBIFG_HND             ; Vector 14: TIMOV Flag
...                   ; Task starts here
RETI                  5

CCIFG_2_HND           ; Vector 4: Module 2
...                   ; Task starts here
RETI                  ; Back to main program 5

; The Module 1 handler shows a way to look if any other
; interrupt is pending: 5 cycles have to be spent, but
; 9 cycles may be saved if another interrupt is pending
CCIFG_1_HND           ; Vector 6: Module 3
...                   ; Task starts here
JMP TB_HND            ; Look for pending ints 2
```
### 12.3 Timer_B Registers

† MSP430x14x, MSP430x16x devices only
The universal synchronous/asynchronous receive/transmit (USART) peripheral interface supports two serial modes with one hardware module. This chapter discusses the operation of the asynchronous UART mode. USART0 is implemented on the MSP430x12xx, MSP430x13xx, and MSP430x15x devices. In addition to USART0, the MSP430x14x and MSP430x16x devices implement a second identical USART module, USART1.

</tbody>
</table>
13.1 USART Introduction: UART Mode

In asynchronous mode, the USART connects the MSP430 to an external system via two external pins, URXD and UTXD. UART mode is selected when the SYNC bit is cleared.

UART mode features include:

- 7- or 8-bit data with odd, even, or non-parity
- Independent transmit and receive shift registers
- Separate transmit and receive buffer registers
- LSB-first data transmit and receive
- Built-in idle-line and address-bit communication protocols for multiprocessor systems
- Receiver start-edge detection for auto-wake up from LPMx modes
- Programmable baud rate with modulation for fractional baud rate support
- Status flags for error detection and suppression and address detection
- Independent interrupt capability for receive and transmit

Figure 13–1 shows the USART when configured for UART mode.
Figure 13–1. USART Block Diagram: UART Mode

* Refer to the device-specific datasheet for SFR locations
13.2 USART Operation: UART Mode

In UART mode, the USART transmits and receives characters at a bit rate asynchronous to another device. Timing for each character is based on the selected baud rate of the USART. The transmit and receive functions use the same baud rate frequency.

13.2.1 USART Initialization and Reset

The USART is reset by a PUC or by setting the SWRST bit. After a PUC, the SWRST bit is automatically set, keeping the USART in a reset condition. When set, the SWRST bit resets the URXIE, UTXIE, URXIFGx, RXWAKE, RXERR, BRK, PE, OE, and FE bits and sets the UTXIFGx and TXEPT bits. The receive and transmit enable flags, URXEx and UTXEx, are not altered by SWRST. Clearing SWRST releases the USART for operation. See also chapter USART Module, I2C mode for USART0 when reconfiguring from I2C mode to UART mode.

**Note: Initializing or Re-Configuring the USART Module**

The required USART initialization/re-configuration process is:

1) Set SWRST (BIS.B #SWRST, &UxCTL)

2) Initialize all USART registers with SWRST = 1 (including UxCTL)

3) Enable USART module via the MEx SFRs (URXEx and/or UTXEx)

4) Clear SWRST via software (BIC.B #SWRST, &UxCTL)

5) Enable interrupts (optional) via the IEx SFRs (URXIE and/or UTXIE)

Failure to follow this process may result in unpredictable USART behavior.

13.2.2 Character Format

The UART character format, shown in Figure 13–2, consists of a start bit, seven or eight data bits, an even/odd/no parity bit, an address bit (address-bit mode), and one or two stop bits. The bit period is defined by the selected clock source and setup of the baud rate registers.

*Figure 13–2. Character Format*
13.2.3 Asynchronous Communication Formats

When two devices communicate asynchronously, the idle-line format is used for the protocol. When three or more devices communicate, the USART supports the idle-line and address-bit multiprocessor communication formats.

Idle-Line Multiprocessor Format

When MM = 0, the idle-line multiprocessor format is selected. Blocks of data are separated by an idle time on the transmit or receive lines as shown in Figure 13–3. An idle receive line is detected when 10 or more continuous ones (marks) are received after the first stop bit of a character. When two stop bits are used for the idle line the second stop bit is counted as the first mark bit of the idle period.

The first character received after an idle period is an address character. The RXWAKE bit is used as an address tag for each block of characters. In the idle-line multiprocessor format, this bit is set when a received character is an address and is transferred to UxRXBUF.

Figure 13–3. Idle-Line Format
The URXWIE bit is used to control data reception in the idle-line multiprocessor format. When the URXWIE bit is set, all non-address characters are assembled but not transferred into the UxRXBUF, and interrupts are not generated. When an address character is received, the receiver is temporarily activated to transfer the character to UxRXBUF and sets the URXIFGx interrupt flag. Any applicable error flag is also set. The user can then validate the received address.

If an address is received, user software can validate the address and must reset URXWIE to continue receiving data. If URXWIE remains set, only address characters will be received. The URXWIE bit is not modified by the USART hardware automatically.

For address transmission in idle-line multiprocessor format, a precise idle period can be generated by the USART to generate address character identifiers on UTXDx. The wake-up temporary (WUT) flag is an internal flag double-buffered with the user-accessible TXWAKE bit. When the transmitter is loaded from UxTXBUF, WUT is also loaded from TXWAKE resetting the TXWAKE bit.

The following procedure sends out an idle frame to indicate an address character will follow:

1) Set TXWAKE, then write any character to UxTXBUF. UxTXBUF must be ready for new data (UTXIFGx = 1).

   The TXWAKE value is shifted to WUT and the contents of UxTXBUF are shifted to the transmit shift register when the shift register is ready for new data. This sets WUT, which suppresses the start, data, and parity bits of a normal transmission, then transmits an idle period of exactly 11 bits. When two stop bits are used for the idle line, the second stop bit is counted as the first mark bit of the idle period. TXWAKE is reset automatically.

2) Write desired address character to UxTXBUF. UxTXBUF must be ready for new data (UTXIFGx = 1).

   The new character representing the specified address is shifted out following the address-identifying idle period on UTXDx. Writing the first “don’t care” character to UxTXBUF is necessary in order to shift the TXWAKE bit to WUT and generate an idle-line condition. This data is discarded and does not appear on UTXDx.
Address-Bit Multiprocessor Format

When \( MM = 1 \), the address-bit multiprocessor format is selected. Each processed character contains an extra bit used as an address indicator shown in Figure 13–4. The first character in a block of characters carries a set address bit which indicates that the character is an address. The USART RXWAKE bit is set when a received character is a valid address character and is transferred to \( UxRXBUF \).

The URXWIE bit is used to control data reception in the address-bit multiprocessor format. If URXWIE is set, data characters (address bit = 0) are assembled by the receiver but are not transferred to \( UxRXBUF \) and no interrupts are generated. When a character containing a set address bit is received, the receiver is temporarily activated to transfer the character to \( UxRXBUF \) and set URXIFGx. All applicable error status flags are also set.

If an address is received, user software must reset URXWIE to continue receiving data. If URXWIE remains set, only address characters (address bit = 1) will be received. The URXWIE bit is not modified by the USART hardware automatically.

**Figure 13–4. Address-Bit Multiprocessor Format**

For address transmission in address-bit multiprocessor mode, the address bit of a character can be controlled by writing to the TXWAKE bit. The value of the TXWAKE bit is loaded into the address bit of the character transferred from \( UxTXBUF \) to the transmit shift register, automatically clearing the TXWAKE bit. TXWAKE must not be cleared by software. It is cleared by USART hardware after it is transferred to WUT or by setting SWRST.
**Automatic Error Detection**

Glitch suppression prevents the USART from being accidentally started. Any low-level on URXDx shorter than the deglitch time $t_\tau$ (approximately 300 ns) will be ignored. See the device-specific datasheet for parameters.

When a low period on URXDx exceeds $t_\tau$ a majority vote is taken for the start bit. If the majority vote fails to detect a valid start bit the USART halts character reception and waits for the next low period on URXDx. The majority vote is also used for each bit in a character to prevent bit errors.

The USART module automatically detects framing errors, parity errors, overrun errors, and break conditions when receiving characters. The bits FE, PE, OE, and BRK are set when their respective condition is detected. When any of these error flags are set, RXERR is also set. The error conditions are described in Table 13–1.

**Table 13–1. Receive Error Conditions**

<table>
<thead>
<tr>
<th>Error Condition</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Framing error</td>
<td>A framing error occurs when a low stop bit is detected. When two stop bits are used, only the first stop bit is checked for framing error. When a framing error is detected, the FE bit is set.</td>
</tr>
<tr>
<td>Parity error</td>
<td>A parity error is a mismatch between the number of 1s in a character and the value of the parity bit. When an address bit is included in the character, it is included in the parity calculation. When a parity error is detected, the PE bit is set.</td>
</tr>
<tr>
<td>Receive overrun error</td>
<td>An overrun error occurs when a character is loaded into UxRXBUF before the prior character has been read. When an overrun occurs, the OE bit is set.</td>
</tr>
<tr>
<td>Break condition</td>
<td>A break condition is a period of 10 or more low bits received on URXDx after a missing stop bit. When a break condition is detected, the BRK bit is set. A break condition can also set the interrupt flag URXIFGx.</td>
</tr>
</tbody>
</table>

When URXEIE = 0 and a framing error, parity error, or break condition is detected, no character is received into UxRXBUF. When URXEIE = 1, characters are received into UxRXBUF and any applicable error bit is set.

When any of the FE, PE, OE, BRK, or RXERR bits is set, the bit remains set until user software resets it or UxRXBUF is read.
13.2.4 USART Receive Enable

The receive enable bit, URXEx, enables or disables data reception on URXDx as shown in Figure 13–5. Disabling the USART receiver stops the receive operation following completion of any character currently being received or immediately if no receive operation is active. The receive-data buffer, UxRXBUF, contains the character moved from the RX shift register after the character is received.

**Figure 13–5. State Diagram of Receiver Enable**

![State Diagram of Receiver Enable](image)

**Note: Re-Enabling the Receiver (Setting URXEx): UART Mode**

When the receiver is disabled (URXEx = 0), re-enabling the receiver (URXEx = 1) is asynchronous to any data stream that may be present on URXDx at the time. Synchronization can be performed by testing for an idle line condition before receiving a valid character (see URXWIE).
**13.2.5 USART Transmit Enable**

When UTXEx is set, the UART transmitter is enabled. Transmission is initiated by writing data to UxTXBUF. The data is then moved to the transmit shift register on the next BITCLK after the TX shift register is empty, and transmission begins. This process is shown in Figure 13–6.

When the UTXEx bit is reset the transmitter is stopped. Any data moved to UxTXBUF and any active transmission of data currently in the transmit shift register prior to clearing UTXEx will continue until all data transmission is completed.

*Figure 13–6. State Diagram of Transmitter Enable*

When the transmitter is enabled (UTXEx = 1), data should not be written to UxTXBUF unless it is ready for new data indicated by UTXIFGx = 1. Violation can result in an erroneous transmission if data in UxTXBUF is modified as it is being moved into the TX shift register.

It is recommended that the transmitter be disabled (UTXEx = 0) only after any active transmission is complete. This is indicated by a set transmitter empty bit (TXEPT = 1). Any data written to UxTXBUF while the transmitter is disabled will be held in the buffer but will not be moved to the transmit shift register or transmitted. Once UTXEx is set, the data in the transmit buffer is immediately loaded into the transmit shift register and character transmission resumes.
13.2.6 UART Baud Rate Generation

The USART baud rate generator is capable of producing standard baud rates from non-standard source frequencies. The baud rate generator uses one prescaler/divider and a modulator as shown in Figure 13–7. This combination supports fractional divisors for baud rate generation. The maximum USART baud rate is one-third the UART source clock frequency BRCLK.

Figure 13–7. MSP430 Baud Rate Generator

Timing for each bit is shown in Figure 13–8. For each bit received, a majority vote is taken to determine the bit value. These samples occur at the N/2–1, N/2, and N/2+1 BRCLK periods, where N is the number of BRCLKs per BITCLK.

Figure 13–8. BITCLK Baud Rate Timing
**USART Operation: UART Mode**

**Baud Rate Bit Timing**

The first stage of the baud rate generator is the 16-bit counter and comparator. At the beginning of each bit transmitted or received, the counter is loaded with INT(N/2) where N is the value stored in the combination of UxBR0 and UxBR1. The counter reloads INT(N/2) for each bit period half-cycle, giving a total bit period of N BRCLKs. For a given BRCLK clock source, the baud rate used determines the required division factor N:

\[ N = \frac{\text{BRCLK}}{\text{baud rate}} \]

The division factor N is often a non-integer value of which the integer portion can be realized by the prescaler/divider. The second stage of the baud rate generator, the modulator, is used to meet the fractional part as closely as possible. The factor N is then defined as:

\[ N = UxBR + \frac{1}{n} \sum_{i=0}^{n-1} m_i \]

Where:

- \( N \): Target division factor
- \( UxBR \): 16-bit representation of registers UxBR0 and UxBR1
- \( i \): Bit position in the character
- \( n \): Total number of bits in the character
- \( m_i \): Data of each corresponding modulation bit (1 or 0)

The BITCLK can be adjusted from bit to bit with the modulator to meet timing requirements when a non-integer divisor is needed. Timing of each bit is expanded by one BRCLK clock cycle if the modulator bit \( m_i \) is set. Each time a bit is received or transmitted, the next bit in the modulation control register determines the timing for that bit. A set modulation bit increases the division factor by one while a cleared modulation bit maintains the division factor given by UxBR.

The timing for the start bit is determined by UxBR plus \( m_0 \), the next bit is determined by UxBR plus \( m_1 \), and so on. The modulation sequence begins with the LSB. When the character is greater than 8 bits, the modulation sequence restarts with \( m_0 \) and continues until all bits are processed.

**Determining the Modulation Value**

Determining the modulation value is an interactive process. Using the timing error formula provided, beginning with the start bit, the individual bit errors are calculated with the corresponding modulator bit set and cleared. The modulation bit setting with the lower error is selected and the next bit error is calculated. This process is continued until all bit errors are minimized. When a character contains more than 8 bits, the modulation bits repeat. For example, the 9th bit of a character uses modulation bit 0.
Transmit Bit Timing

The timing for each character is the sum of the individual bit timings. By modulating each bit, the cumulative bit error is reduced. The individual bit error can be calculated by:

\[
\text{Error [%]} = \left\{ \frac{\text{baud rate}}{\text{BRCLK}} \times \left[ (j + 1) \times \text{UxBR} + \sum_{i=0}^{n-1} m_i \right] - (j + 1) \right\} \times 100\%
\]

With:

- **baud rate**: Desired baud rate
- **BRCLK**: Input frequency – UCLKI, ACLK, or SMCLK
- **UxBR**: Division factor in registers UxBR1 and UxBR0
- **j**: Bit position - 0 for the start bit, 1 for data bit D0, and so on

For example, the transmit errors for the following conditions are calculated:

- **Baud rate**: 2400
- **BRCLK**: 32,768 Hz (ACLK)
- **UxBR**: 13, since the ideal division factor is 13.65
- **UxMCTL**: 6Bh: m7 = 0, m6 = 1, m5 = 1, m4 = 0, m3 = 1, m2 = 0, m1 = 1, and m0 = 1. The LSB of UxMCTL is used first.

For example, the transmit errors for the following conditions are calculated:

- **Start bit Error [%]** = \left\{ \frac{\text{baud rate}}{\text{BRCLK}} \times ((0 + 1) \times \text{UxBR} + 1) - 1 \right\} \times 100\% = 2.54%
- **Data bit D0 Error [%]** = \left\{ \frac{\text{baud rate}}{\text{BRCLK}} \times ((1 + 1) \times \text{UxBR} + 2) - 2 \right\} \times 100\% = 5.08%
- **Data bit D1 Error [%]** = \left\{ \frac{\text{baud rate}}{\text{BRCLK}} \times ((2 + 1) \times \text{UxBR} + 2) - 3 \right\} \times 100\% = 0.29%
- **Data bit D2 Error [%]** = \left\{ \frac{\text{baud rate}}{\text{BRCLK}} \times ((3 + 1) \times \text{UxBR} + 3) - 4 \right\} \times 100\% = 2.83%
- **Data bit D3 Error [%]** = \left\{ \frac{\text{baud rate}}{\text{BRCLK}} \times ((4 + 1) \times \text{UxBR} + 3) - 5 \right\} \times 100\% = -1.95%
- **Data bit D4 Error [%]** = \left\{ \frac{\text{baud rate}}{\text{BRCLK}} \times ((5 + 1) \times \text{UxBR} + 4) - 6 \right\} \times 100\% = 0.59%
- **Data bit D5 Error [%]** = \left\{ \frac{\text{baud rate}}{\text{BRCLK}} \times ((6 + 1) \times \text{UxBR} + 5) - 7 \right\} \times 100\% = 3.13%
- **Data bit D6 Error [%]** = \left\{ \frac{\text{baud rate}}{\text{BRCLK}} \times ((7 + 1) \times \text{UxBR} + 5) - 8 \right\} \times 100\% = -1.66%
- **Data bit D7 Error [%]** = \left\{ \frac{\text{baud rate}}{\text{BRCLK}} \times ((8 + 1) \times \text{UxBR} + 6) - 9 \right\} \times 100\% = 0.88%
- **Parity bit Error [%]** = \left\{ \frac{\text{baud rate}}{\text{BRCLK}} \times ((9 + 1) \times \text{UxBR} + 7) - 10 \right\} \times 100\% = 3.42%
- **Stop bit 1 Error [%]** = \left\{ \frac{\text{baud rate}}{\text{BRCLK}} \times ((10 + 1) \times \text{UxBR} + 7) - 11 \right\} \times 100\% = -1.37%

The results show the maximum per-bit error to be 5.08% of a BITCLK period.
Receive Bit Timing

Receive timing consists of two error sources. The first is the bit-to-bit timing error. The second is the error between a start edge occurring and the start edge being accepted by the USART. Figure 13–9 shows the asynchronous timing errors between data on the URXDx pin and the internal baud-rate clock.

**Figure 13–9. Receive Error**

The ideal start bit timing $t_{\text{ideal}(0)}$ is half the baud-rate timing $t_{\text{baud rate}}$ because the bit is tested in the middle of its period. The ideal baud rate timing $t_{\text{ideal}(i)}$ for the remaining character bits is the baud rate timing $t_{\text{baud rate}}$. The individual bit errors can be calculated by:

$$\text{Error} \ [%\] = \left( \frac{\text{baud rate}}{\text{BRCLK}} \times \left[ 2 \times \left( m_0 + \text{int} \left( \frac{UxBR}{2} \right) \right) + \left( i \times UxBR + \sum_{i=1}^{n-1} m_i \right) \right] - 1 - j \right) \times 100\%$$

Where:

- **baud rate** is the required baud rate
- **BRCLK** is the input frequency—selected for UCLK, ACLK, or SMCLK
- $j = 0$ for the start bit, 1 for data bit D0, and so on
- $UxBR$ is the division factor in registers $UxBR1$ and $UxBR0$
For example, the receive errors for the following conditions are calculated:

Baud rate = 2400
BRCLK = 32,768 Hz (ACLK)
UxBR = 13, since the ideal division factor is 13.65
UxMCTL = 6B:m7=0, m6=1, m5=1, m4=0, m3=1, m2=0, m1=1 and m0=1 The LSB of UxMCTL is used first.

\[
\text{Start bit Error [\%]} = \left( \frac{\text{baud rate}}{\text{BRCLK}} \times [2x(1 + 6) + (0 \times \text{UxBR} + 0)] - 1 - 0 \right) \times 100\% = 2.54\%
\]

\[
\text{Data bit D0 Error [\%]} = \left( \frac{\text{baud rate}}{\text{BRCLK}} \times [2x(1 + 6) + (1 \times \text{UxBR} + 1)] - 1 - 1 \right) \times 100\% = 5.08\%
\]

\[
\text{Data bit D1 Error [\%]} = \left( \frac{\text{baud rate}}{\text{BRCLK}} \times [2x(1 + 6) + (2 \times \text{UxBR} + 1)] - 1 - 2 \right) \times 100\% = 0.29\%
\]

\[
\text{Data bit D2 Error [\%]} = \left( \frac{\text{baud rate}}{\text{BRCLK}} \times [2x(1 + 6) + (3 \times \text{UxBR} + 2)] - 1 - 3 \right) \times 100\% = 2.83\%
\]

\[
\text{Data bit D3 Error [\%]} = \left( \frac{\text{baud rate}}{\text{BRCLK}} \times [2x(1 + 6) + (4 \times \text{UxBR} + 2)] - 1 - 4 \right) \times 100\% = -1.95\%
\]

\[
\text{Data bit D4 Error [\%]} = \left( \frac{\text{baud rate}}{\text{BRCLK}} \times [2x(1 + 6) + (5 \times \text{UxBR} + 3)] - 1 - 5 \right) \times 100\% = 0.59\%
\]

\[
\text{Data bit D5 Error [\%]} = \left( \frac{\text{baud rate}}{\text{BRCLK}} \times [2x(1 + 6) + (6 \times \text{UxBR} + 4)] - 1 - 6 \right) \times 100\% = 3.13\%
\]

\[
\text{Data bit D6 Error [\%]} = \left( \frac{\text{baud rate}}{\text{BRCLK}} \times [2x(1 + 6) + (7 \times \text{UxBR} + 4)] - 1 - 7 \right) \times 100\% = -1.66\%
\]

\[
\text{Data bit D7 Error [\%]} = \left( \frac{\text{baud rate}}{\text{BRCLK}} \times [2x(1 + 6) + (8 \times \text{UxBR} + 5)] - 1 - 8 \right) \times 100\% = 0.88\%
\]

\[
\text{Parity bit Error [\%]} = \left( \frac{\text{baud rate}}{\text{BRCLK}} \times [2x(1 + 6) + (9 \times \text{UxBR} + 6)] - 1 - 9 \right) \times 100\% = 3.42\%
\]

\[
\text{Stop bit 1 Error [\%]} = \left( \frac{\text{baud rate}}{\text{BRCLK}} \times [2x(1 + 6) + (10 \times \text{UxBR} + 6)] - 1 - 10 \right) \times 100\% = -1.37\%
\]

The results show the maximum per-bit error to be 5.08% of a BITCLK period.
Typical Baud Rates and Errors

Standard baud rate frequency data for UxBRx and UxMCTL are listed in Table 13–2 for a 32,768-Hz watch crystal (ACLK) and a typical 1,048,576-Hz SMCLK.

The receive error is the accumulated time versus the ideal scanning time in the middle of each bit. The transmit error is the accumulated timing error versus the ideal time of the bit period.

13.2.7 USART Interrupts

The USART has one interrupt vector for transmission and one interrupt vector for reception.

**USART Transmit Interrupt Operation**

The UTXIFGx interrupt flag is set by the transmitter to indicate that UxTXBUF is ready to accept another character. An interrupt request is generated if UTXIEx and GIE are also set. UTXIFGx is automatically reset if the interrupt request is serviced or if a character is written to UxTXBUF.

UTXIFGx is set after a PUC or when SWRST = 1. UTXIEx is reset after a PUC or when SWRST = 1. The operation is shown in Figure 13–10.

*Figure 13–10. Transmit Interrupt Operation*
**USART Operation: UART Mode**

**USART Receive Interrupt Operation**

The URXIFGx interrupt flag is set each time a character is received and loaded into UxRXBUF. An interrupt request is generated if URXIE is enabled and GIE is also enabled. URXIFGx and URXIE are reset by a system reset PUC signal or when SWRST = 1. URXIFGx is automatically reset if the pending interrupt is served (when URXSE = 0) or when UxRXBUF is read. The operation is shown in Figure 13–11.

**Figure 13–11. Receive Interrupt Operation**

URXEIE is used to enable or disable erroneous characters from setting URXIFGx. When using multiprocessor addressing modes, URXWIE is used to auto-detect valid address characters and reject unwanted data characters.

Two types of characters do not set URXIFGx:

- Erroneous characters when URXEIE = 0
- Non-address characters when URXWIE = 1

When URXEIE = 1 a break condition will set the BRK bit and the URXIFGx flag.
Receive-Start Edge Detect Operation

The URXSE bit enables the receive start-edge detection feature. The recommended usage of the receive-start edge feature is when BRCLK is sourced by the DCO and when the DCO is off because of low-power mode operation. The ultra-fast turn-on of the DCO allows character reception after the start edge detection.

When URXSE, URXIEx and GIE are set and a start edge occurs on URXDx, the internal signal URXS will be set. When URXS is set, a receive interrupt request is generated but URXIFGx is not set. User software in the receive interrupt service routine can test URXIFGx to determine the source of the interrupt. When URXIFGx = 0 a start edge was detected and when URXIFGx = 1 a valid character (or break) was received.

When the ISR determines the interrupt request was from a start edge, user software toggles URXSE, and must enable the BRCLK source by returning from the ISR to active mode or to a low-power mode where the source is active. If the ISR returns to a low-power mode where the BRCLK source is inactive, the character will not be received. Toggling URXSE clears the URXS signal and re-enables the start edge detect feature for future characters. See chapter System Resets, Interrupts, and Operating Modes for information on entering and exiting low-power modes.

The now active BRCLK allows the USART to receive the balance of the character. After the full character is received and moved to UxRXBUF, URXIFGx is set and an interrupt service is again requested. Upon ISR entry, URXIFGx = 1 indicating a character was received. The URXIFGx flag is cleared when user software reads UxRXBUF.

BIC #SCG0+SCG1,0(SP) ; Enable BRCLK = DCO
RETI ;

**Note:** Break Detect With Halted UART Clock

When using the receive start-edge detect feature a break condition cannot be detected when the BRCLK source is off.
**Receive-Start Edge Detect Conditions**

When URXSE = 1, glitch suppression prevents the USART from being accidentally started. Any low-level on URXDx shorter than the deglitch time $t_\tau$ (approximately 300 ns) will be ignored by the USART and no interrupt request will be generated as shown in Figure 13–12. See the device-specific datasheet for parameters.

*Figure 13–12. Glitch Suppression, USART Receive Not Started*

---

When a glitch is longer than $t_\tau$, or a valid start bit occurs on URXDx, the USART receive operation is started and a majority vote is taken as shown in Figure 13–13. If the majority vote fails to detect a start bit the USART halts character reception.

If character reception is halted, an active BRCLK is not necessary. A time-out period longer than the character receive duration can be used by software to indicate that a character was not received in the expected time and the software can disable BRCLK.

*Figure 13–13. Glitch Suppression, USART Activated*
### 13.3 USART Registers: UART Mode

Table 13–3 lists the registers for all devices implementing a USART module.
Table 13–4 applies only to devices with a second USART module, USART1.

USART Peripheral Interface, SPI Mode

The universal synchronous/asynchronous receive/transmit (USART) peripheral interface supports two serial modes with one hardware module. This chapter discusses the operation of the synchronous peripheral interface or SPI mode. USART0 is implemented on the MSP430x12xx, MSP430x13xx, and MSP430x15x devices. In addition to USART0, the MSP430x14x and MSP430x16x devices implement a second identical USART module, USART1.

</tr>
</tbody>
</table>
14.1 USART Introduction: SPI Mode

In synchronous mode, the USART connects the MSP430 to an external system via three or four pins: SIMO, SOMI, UCLK, and STE. SPI mode is selected when the SYNC bit is set and the I2C bit is cleared.

SPI mode features include:

- 7- or 8-bit data length
- 3-pin and 4-pin SPI operation
- Master or slave modes
- Independent transmit and receive shift registers
- Separate transmit and receive buffer registers
- Selectable UCLK polarity and phase control
- Programmable UCLK frequency in master mode
- Independent interrupt capability for receive and transmit

Figure 14–1 shows the USART when configured for SPI mode.
Figure 14–1. USART Block Diagram: SPI Mode

* Refer to the device-specific datasheet for SFR locations.
14.2 USART Operation: SPI Mode

In SPI mode, serial data is transmitted and received by multiple devices using a shared clock provided by the master. An additional pin, STE, is provided to enable a device to receive and transmit data and is controlled by the master.

Three or four signals are used for SPI data exchange:

- **SIMO**: Slave in, master out
  - Master mode: SIMO is the data output line.
  - Slave mode: SIMO is the data input line.

- **SOMI**: Slave out, master in
  - Master mode: SOMI is the data input line.
  - Slave mode: SOMI is the data output line.

- **UCLK**: USART SPI clock
  - Master mode: UCLK is an output.
  - Slave mode: UCLK is an input.

- **STE**: Slave transmit enable. Used in 4-pin mode to allow multiple masters on a single bus. Not used in 3-pin mode.
  - 4-Pin master mode:
    - When STE is high, SIMO and UCLK operate normally.
    - When STE is low, SIMO and UCLK are set to the input direction.
  - 4-pin slave mode:
    - When STE is high, RX/TX operation of the slave is disabled and SOMI is forced to the input direction.
    - When STE is low, RX/TX operation of the slave is enabled and SOMI operates normally.

14.2.1 USART Initialization and Reset

The USART is reset by a PUC or by the SWRST bit. After a PUC, the SWRST bit is automatically set, keeping the USART in a reset condition. When set, the SWRST bit resets the URXIEx, UTXIEx, URXIFGx, OE, and FE bits and sets the UTXIFGx flag. The USPIEx bit is not altered by SWRST. Clearing SWRST releases the USART for operation. See also chapter *USART Module, I2C mode* for USART0 when reconfiguring from I2C mode to SPI mode.

**Note: Initializing or Re-Configuring the USART Module**

The required USART initialization/re-configuration process is:

1) Set SWRST (`BIS.B #SWRST,&UxCTL`)
2) Initialize all USART registers with SWRST=1 (including UxCTL)
3) Enable USART module via the MEx SFRs (USPIEx)
4) Clear SWRST via software (`BIC.B #SWRST,&UxCTL`)
5) Enable interrupts (optional) via the IEx SFRs (URXIEx and/or UTXIEx)

Failure to follow this process may result in unpredictable USART behavior.
14.2.2 Master Mode

Figure 14–2. USART Master and External Slave

Figure 14–2 shows the USART as a master in both 3-pin and 4-pin configurations. The USART initiates data transfer when data is moved to the transmit data buffer UxTXBUF. The UxTXBUF data is moved to the TX shift register when the TX shift register is empty, initiating data transfer on SIMO starting with the most-significant bit. Data on SOMI is shifted into the receive shift register on the opposite clock edge, starting with the most-significant bit. When the character is received, the receive data is moved from the RX shift register to the received data buffer UxRXBUF and the receive interrupt flag, URXIFGx, is set, indicating the RX/TX operation is complete.

A set transmit interrupt flag, UTXIFGx, indicates that data has moved from UxTXBUF to the TX shift register and UxTXBUF is ready for new data. It does not indicate RX/TX completion.

To receive data into the USART in master mode, data must be written to UxTXBUF because receive and transmit operations operate concurrently.

Four-Pin SPI Master Mode

In 4-pin master mode, STE is used to prevent conflicts with another master. The master operates normally when STE is high. When STE is low:

- SIMO and UCLK are set to inputs and no longer drive the bus
- The error bit FE is set indicating a communication integrity violation to be handled by the user

A low STE signal does not reset the USART module. The STE input signal is not used in 3-pin master mode.
14.2.3 Slave Mode

*Figure 14–3. USART Slave and External Master*

Figure 14–3 shows the USART as a slave in both 3-pin and 4-pin configurations. UCLK is used as the input for the SPI clock and must be supplied by the external master. The data-transfer rate is determined by this clock and not by the internal baud rate generator. Data written to UxTXBUF and moved to the TX shift register before the start of UCLK is transmitted on SOMI. Data on SIMO is shifted into the receive shift register on the opposite edge of UCLK and moved to UxRXBUF when the set number of bits are received. When data is moved from the RX shift register to UxRXBUF, the URXIFGx interrupt flag is set, indicating that data has been received. The overrun error bit, OE, is set when the previously received data is not read from UxRXBUF before new data is moved to UxRXBUF.

**Four-Pin SPI Slave Mode**

In 4-pin slave mode, STE is used by the slave to enable the transmit and receive operations and is provided by the SPI master. When STE is low, the slave operates normally. When STE is high:

- Any receive operation in progress on SIMO is halted
- SOMI is set to the input direction

A high STE signal does not reset the USART module. The STE input signal is not used in 3-pin slave mode.
14.2.4 SPI Enable

The SPI transmit/receive enable bit USPIEx enables or disables the USART in SPI mode. When USPIEx = 0, the USART stops operation after the current transfer completes, or immediately if no operation is active. A PUC or set SWRST bit disables the USART immediately and any active transfer is terminated.

Transmit Enable

When USPIEx = 0, any further write to UxTXBUF does not transmit. Data written to UxTXBUF will begin to transmit when USPIEx = 1 and the BRCLK source is active. Figure 14–4 and Figure 14–5 show the transmit enable state diagrams.

Figure 14–4. Master Mode Transmit Enable

Figure 14–5. Slave Transmit Enable State Diagram
USART Operation: SPI Mode

Receive Enable

The SPI receive enable state diagrams are shown in Figure 14–6 and Figure 14–7. When USPIEx = 0, UCLK is disabled from shifting data into the RX shift register.

Figure 14–6. SPI Master Receive-Enable State Diagram

Figure 14–7. SPI Slave Receive-Enable State Diagram
14.2.5 Serial Clock Control

UCLK is provided by the master on the SPI bus. When MM = 1, BITCLK is provided by the USART baud rate generator on the UCLK pin as shown in Figure 14–8. When MM = 0, the USART clock is provided on the UCLK pin by the master and, the baud rate generator is not used and the SSELx bits are don’t care. The SPI receiver and transmitter operate in parallel and use the same clock source for data transfer.

Figure 14–8. SPI Baud Rate Generator

The 16-bit value of UxBR0+UxBR1 is the division factor of the USART clock source, BRCLK. The maximum baud rate that can be generated in master mode is BRCLK/2. The modulator in the USART baud rate generator is not used for SPI mode and is recommended to be set to 000h. The UCLK frequency is given by:

\[
\text{Baud rate} = \frac{BRCLK}{UxBR} \text{ with } UxBR = [UxBR1, UxBR0]
\]
**Serial Clock Polarity and Phase**

The polarity and phase of UCLK are independently configured via the CKPL and CKPH control bits of the USART. Timing for each case is shown in Figure 14–9.

14.2.6 SPI Interrupts

The USART has one interrupt vector for transmission and one interrupt vector for reception.

SPI Transmit Interrupt Operation

The UTXIFGx interrupt flag is set by the transmitter to indicate that UxTXBUF is ready to accept another character. An interrupt request is generated if UTXIEx and GIE are also set. UTXIFGx is automatically reset if the interrupt request is serviced or if a character is written to UxTXBUF.

UTXIFGx is set after a PUC or when SWRST = 1. UTXIEx is reset after a PUC or when SWRST = 1. The operation is shown in Figure 14–10.

Figure 14–10. Transmit Interrupt Operation

---

Note: Writing to UxTXBUF in SPI Mode

Data written to UxTXBUF when UTXIFGx = 0 and USPIEx = 1 may result in erroneous data transmission.
**SPI Receive Interrupt Operation**

The URXIFGx interrupt flag is set each time a character is received and loaded into UxRXBUF as shown in Figure 14–11 and Figure 14–12. An interrupt request is generated if URXIEx and GIE are also set. URXIFGx and URXIEx are reset by a system reset PUC signal or when SWRST = 1. URXIFGx is automatically reset if the pending interrupt is served or when UxRXBUF is read.

Note: Modifying the SFR bits

To avoid modifying control bits for other modules, it is recommended to set or clear the IEX and IFGx bits using BIS.B or BIC.B instructions, rather than MOV.B or CLR.B instructions.

**UxMCTLx**

The modulation control register is not used for SPI mode and should be set to 000h.
### USART Registers: SPI Mode

#### UxRXBUF, USART Receive Buffer Register

<table>
<thead>
<tr>
<th></th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>2^7</td>
<td>2^6</td>
<td>2^5</td>
<td>2^4</td>
<td>2^3</td>
<td>2^2</td>
<td>2^1</td>
<td>2^0</td>
</tr>
</tbody>
</table>

The receive-data buffer is user accessible and contains the last received character from the receive shift register. Reading UxRXBUF resets the OE bit and URXIFGx flag. In 7-bit data mode, UxRXBUF is LSB justified and the MSB is always reset.

#### UxTXBUF, USART Transmit Buffer Register

<table>
<thead>
<tr>
<th></th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

The transmit data buffer is user accessible and contains current data to be transmitted. When seven-bit character-length is used, the data should be MSB justified before being moved into UxTXBUF. Data is transmitted MSB first. Writing to UxTXBUF clears UTXIFGx.
### ME1, Module Enable Register 1

‡ MSP430x12xx devices only
The universal synchronous/asynchronous receive/transmit (USART) peripheral interface supports I²C communication in USART0. This chapter describes the I²C mode. The I²C mode is implemented on the MSP430x15x and MSP430x16x devices.
15.1 I²C Module Introduction

The inter-IC control (I²C) module provides an interface between the MSP430 and I²C-compatible devices connected by way of the two-wire I²C serial bus. External components attached to the I²C bus serially transmit and/or receive serial data to/from the USART through the 2-wire I²C interface.

The I²C module has the following features:

- Compliance to the Philips Semiconductor I²C specification v2.1
  - Byte/word format transfer
  - 7-bit and 10-bit device addressing modes
  - General call
  - Start/restart/stop
  - Multi-master transmitter/slave receiver mode
  - Multi-master receiver/slave transmitter mode
  - Combined master transmit/receive and receive/transmit mode
  - Standard mode up to 100 kbps and fast mode up to 400 kbps support

- Built-in FIFO for buffered read and write

- Programmable clock generation

- 16-bit wide data access to maximize bus throughput

- Automatic data byte counting

- Designed for low power

- Slave receiver START detection for auto-wake up from LPMx modes

- Extensive interrupt capability

- Implemented on USART0 only

The I²C block diagram is shown in Figure 15–1.
Figure 15–1. USART Block Diagram: I²C Mode
15.2 I^2C Module Operation

The I^2C module supports any slave or master I^2C-compatible device. Figure 15–2 shows an example of an I^2C bus. Each I^2C device is recognized by a unique address and can operate as either a transmitter or a receiver. A device connected to the I^2C bus can be considered as the master or the slave when performing data transfers. A master initiates a data transfer and generates the clock signal SCL. Any device addressed by a master is considered a slave.

I^2C data is communicated using the serial data pin (SDA) and the serial clock pin (SCL). Both SDA and SCL are bidirectional, and must be connected to a positive supply voltage using a pull-up resistor.

Figure 15–2. I^2C Bus Connection Diagram

Note: SDA and SCL Levels

The MSP430 SDA and SCL pins must not be pulled up above the MSP430 V_{CC} level.
15.2.1 I²C Module Initialization

The I²C module is part of the USART peripheral. Individual bit definitions when using USART0 in I²C mode are different from that in SPI or UART mode. The default value for the U0CTL register is the UART mode. To select I²C operation the SYNC and I2C bits must be set. After module initialization, the I²C module is ready for transmit or receive operation. Setting I2CEN releases the I²C module for operation.

Configuring and re-configuring the I²C module must be done when I2CEN = 0 to avoid unpredictable behavior. Setting I2CEN = 0 has the following effects:

- I²C communication stops
- SDA and SCL are high impedance
- I2CTCTL, bits 3-0 are cleared and bits 7-4 are unchanged
- I2CDCTL and I2CDR register is cleared
- Transmit and receive shift registers are cleared
- U0CTL, I2CNAT, I2CPSC, I2CSCL, I2CSCLL registers are unchanged
- I2COA, I2CSA, I2CIE, I2CIFG, and I2CIV registers are unchanged

When re-configuring the USART from I²C mode to UART or SPI mode the I2C, SYNC, and I2CEN bits must first be cleared, then the SWRST must be set and the UART or SPI initialization procedure must be followed. Failure to follow this procedure could result in unpredictable operation.

Note: Configuring the USART Module for I²C Operation After Reset

The required I²C configuration process is:
1) Select I²C mode with SWRST = 1 (BIS.B #I2C + SYNC,&U0CTL)
2) Disable the I²C module (BIC.B #I2CEN,&U0CTL)
3) Configure the I²C module with I2CEN = 0
4) Set I2CEN via software (BIS.B #I2CEN,&U0CTL)

Failure to follow this process may result in unpredictable USART behavior.

Note: Re-Configuring the USART Module for UART or SPI Operation

When re-configuring the USART module for UART or SPI operation from I²C operation, the required process is:
1) Clear I2C, SYNC, and I2CEN (CLR.B &U0CTL)
2) Set SWRST (MOV.B #SWRST,&U0CTL)
3) Continue with UART or SPI initialization procedure.

Failure to follow this process may result in unpredictable USART behavior.
15.2.2 I^2C Serial Data

One clock pulse is generated by the master device for each data bit transferred. The I^2C module operates with byte data. Data is transferred most significant bit first as shown in Figure 15–3.

The first byte after a START condition consists of a 7-bit slave address and the R/W bit. When R/W = 0, the master transmits data to a slave. When R/W = 1, the master receives data from a slave. The ACK bit is sent from the receiver after each byte on the 9th SCL clock.

**Figure 15–3. I^2C Module Data Transfer**

START and STOP conditions are generated by the master and are shown in Figure 15–3. A START condition is a high-to-low transition on the SDA line while SCL is high. A STOP condition is a low-to-high transition on the SDA line while SCL is high. The busy bit, I2CBB, is set after a START and cleared after a STOP.

Data on SDA must be stable during the high period of SCL as shown in Figure 15–4. The high and low state of SDA can only change when SCL is low, otherwise start or stop conditions will be generated.

**Figure 15–4. Bit Transfer on the I^2C Bus**
15.2.3 I2C Addressing Modes

The I2C module supports 7-bit and 10-bit addressing modes.

7-Bit Addressing

In the 7-bit addressing format, shown in Figure 15–5, the first byte is the 7-bit slave address and the R/W bit. The ACK bit is sent from the receiver after each byte.

**Figure 15–5. I2C Module 7-Bit Addressing Format**

<table>
<thead>
<tr>
<th>1</th>
<th>8</th>
<th>1</th>
<th>1</th>
<th>8</th>

<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td>Slave Address</td>
<td>R/W</td>
<td>ACK</td>
<td>Data</td>
<td>ACK</td>
<td>Data</td>
</tr>
</tbody>
</table>

10-Bit Addressing

In the 10-bit addressing format, shown in Figure 15–6, the first byte is made up of 11110b plus the two MSBs of the 10-bit slave address and the R/W bit. The ACK bit is sent from the receiver after each byte. The next byte is the remaining 8 bits of the 10-bit slave address, followed by the ACK bit and the 8-bit data.

**Figure 15–6. I2C Module 10-Bit Addressing Format**

<table>
<thead>
<tr>
<th>1</th>
<th>8</th>
<th>1</th>

</thead>
<tbody>
<tr>
<td>S</td>
<td>Slave Address 1st byte</td>
<td>R/W</td>
<td>ACK</td>
<td>Slave Address 2nd byte</td>
<td>ACK</td>
<td>Data</td>
</tr>
</tbody>
</table>

Repeated Start Conditions

The direction of data flow on SDA can be changed by the master, without first stopping a transfer, by issuing a repeated START condition. This is called a RESTART. After a RESTART is issued, the slave address is again sent out with the new data direction specified by the R/W bit. The RESTART condition is shown in Figure 15–7.

**Figure 15–7. I2C Module Addressing Format with Repeated START Condition**

I\textsuperscript{2}C Module Operation

15.2.4 I\textsuperscript{2}C Module Operating Modes

The I\textsuperscript{2}C module operates in master transmitter, master receiver, slave transmitter, or slave receiver mode.

Master Mode

In master mode, transmit and receive operation is controlled with the I\textsuperscript{2}CRM, I\textsuperscript{2}CSTT, and I\textsuperscript{2}CSTP bits as described in Table 15–1. The master transmitter and master receiver modes are shown in Figure 15–8 and Figure 15–9. SCL is held low when the intervention of the CPU is required after a byte has been received or transmitted.

Table 15–1. Master Operation

Arbitration

If two or more master transmitters simultaneously start a transmission on the bus, an arbitration procedure is invoked. Figure 15–10 illustrates the arbitration procedure between two devices. The arbitration procedure uses the data presented on SDA by the competing transmitters. The first master transmitter that generates a logic high is overruled by the opposing master generating a logic low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. The master transmitter that lost arbitration switches to the slave receiver mode, and sets the arbitration lost flag ALIFG. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 15–10. Arbitration Procedure Between Two Master Transmitters

If the arbitration procedure is in progress when a repeated START condition or STOP condition is transmitted on SDA, the master transmitters involved in arbitration must send the repeated START condition or STOP condition at the same position in the format frame. Arbitration is not allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition
**Automatic Data Byte Counting**

Automatic data byte counting is supported in master mode with the I2CNDAT register. When I2CRM = 0, the number of bytes to be received or transmitted is written to I2CNDAT. A STOP condition is automatically generated after I2CNDAT number of bytes have been transferred.

---

**Note: I2CNDAT Register**

Do not change the I2CNDAT register while I2CBB = 1 and I2CRM = 0. Otherwise, unpredictable operation may occur.

---

**Slave Mode**

In slave mode, transmit and receive operations are controlled automatically by the I2C module. The slave transmitter and slave receiver modes are shown in Figure 15–11 and Figure 15–12.

In slave receiver mode, serial data bits received on SDA are shifted in with the clock pulses that are generated by the master device. The slave device does not generate the clock, but it can hold SCL low if intervention of the CPU is required after a byte has been received.

Slave transmitter mode is entered when the slave address byte transmitted by the master is the same as its own address and a set R/W bit has been transmitted indicating a request to send data to the master. The slave transmitter shifts the serial data out on SDA with the clock pulses that are generated by the master device. The slave device does not generate the clock, but it will hold SCL low while intervention of the CPU is required after a byte has been transmitted.

---

**Note: I2CTRX Bit In Slave Mode**

The I2CTRX bit must be cleared for proper slave mode operation.

15.2.5 The I²C Data Register I2CDR

The I2CDR register can be accessed as an 8-bit or 16-bit register selected by the I2CWORD bit. The I2CDR register functions as described in Table 15–2. When I2CWORD = 1, any attempt to modify the register with a byte instruction will fail and the register will not be modified.

Table 15–2. I2CDR Register Function

<table>
<thead>
<tr>
<th>I2CWORD</th>
<th>I2CTRX</th>
<th>I2CDR Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td><em>Byte mode transmit:</em> Only the low byte is used. The byte is double buffered. If a new byte is written before the previous byte has been transmitted, the new byte is held in a temporary buffer before being latched into the I2CDR low byte. TXRDYIFG is set when I2CDR is ready to be accessed.</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td><em>Byte mode receive:</em> Only the low byte is used. The byte is double buffered. If a new byte is received before the previous byte has been read, the new byte is held in a temporary buffer before being latched into the I2CDR low byte. RXRDYIFG is set when I2CDR is ready to be read.</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td><em>Word mode transmit:</em> The low byte of the word is sent first, then the high byte. The register is double buffered. If a new word is written before the previous word has been transmitted, the new word is held in a temporary buffer before being latched into the I2CDR register. TXRDYIFG is set when I2CDR is ready to be accessed.</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td><em>Word mode receive:</em> The low byte of the word was received first, then the high byte. The register is double buffered. If a new word is received before the previous word has been read, the new word is held in a temporary buffer before being latched into the I2CDR register. RXRDYIFG is set when I2CDR is ready to be accessed.</td>
</tr>
</tbody>
</table>

Transmit Underflow

In master mode, underflow occurs when the transmit shift register and the transmit buffer are empty. In slave mode, underflow occurs when the transmit shift register and the transmit buffer are empty and the external I²C master still requests data. When transmit underflow occurs, the I2CTXUDF bit is set. Writing data to the I2CDR register or resetting the I2CEN bit resets I2CTXUDF. I2CTXUDF is used in transmit mode only.

Receive Overrun

Receive overrun occurs when the receive shift register is full and the receive buffer is full. The I2CRXOVR bit is set when receive overrun occurs. No data is lost because SCL is held low in this condition, which stops further bus activity. Reading the I2CDR register or resetting I2CEN resets I2CRXOVR. The I2CRXOVR bit is used in receive mode only.
15.2.6 I²C Clock Generation and Synchronization

The I²C module is operated with the clock source selected by the I2CSSELx bits. The prescaler, I2CPSC, and the I2CSCLH and I2CSCLL registers determine the frequency and duty cycle of the SCL clock signal for master mode as shown in Figure 15–13.

**Note: I²CCLK Maximum Frequency**

The I²C module clock source I2CIN must be at least 10x the SCL frequency in both master and slave modes. This condition is met automatically in master mode by the I2CSCLL and I2CSCLH registers.

**Note: I2CPSC Value**

When I2CPSC > 4, unpredictable operation can result. The I2CSCLL and I2CSCLH registers should be used to set the SCL frequency.

Figure 15–13. I²C Module SCL Generation

During the arbitration procedure the clocks from the different masters must be synchronized. A device that first generates a low period on SCL overrules the other devices forcing them to start their own low periods. SCL is then held low by the device with the longest low period. The other devices must wait for SCL to be released before starting their high periods. Figure 15–14 illustrates the clock synchronization. This allows a slow slave to slow down a fast master.

Figure 15–14. Synchronization of Two I²C Clock Generators During Arbitration
15.2.7 Using the I²C Module with Low Power Modes

The I²C module can be used with MSP430 low-power modes. When the internal clock source for the I²C module is present, the module operates normally regardless of the MSP430 operating mode. When the internal clock source for the I²C module is not present, automatic clock activation is provided. When the I²C module is in the idle state, I2CBUSY = 0, and the I²C clock source I2CIN is disconnected from the I²C module state machine, saving power.

When the I²C clock source is inactive, the I²C module automatically activates the selected clock source when needed, regardless of the control-bit settings for the clock source. The clock source remains active until the I²C module returns to idle condition. After the I²C module returns to the idle condition, control of the clock-source reverts to the settings of its control bits.

Automatic I²C clock activation occurs when:

- In master mode, clock activation occurs when I2CSTT = 1 and remains active until the transfer completes and the I²C module returns to the idle condition.

- In slave mode, clock activation occurs when a START condition is detected and remains active until the transfer completes and the I²C module returns to the idle condition. After detection of the START condition, the STTIFG flag is set, and the module holds the SCL line low until the clock source becomes active. Once the source is active, the I²C module releases the SCL line to the master.

When the I²C module activates an inactive clock source, the clock source becomes active for the whole device and any peripheral configured to use the clock source may be affected. For example, a timer using SMCLK will increment while the I²C module forces SMCLK active.
### 15.2.8 I²C Interrupts

The I²C module has one interrupt vector for eight interrupt flags listed in Table 15–3. Each interrupt flag has its own interrupt enable bit. When an interrupt is enabled, and the GIE bit is set, the interrupt flag will generate an interrupt request.

**Table 15–3. I²C Interrupts**

<table>
<thead>
<tr>
<th>Interrupt Flag</th>
<th>Interrupt Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALIFG</td>
<td>Arbitration-lost. Arbitration can be lost when two or more transmitters start a transmission simultaneously, or when the software attempts to initiate an I²C transfer while I2CBB = 1. The ALIFG flag is set when arbitration has been lost. When ALIFG is set the MST and I2CSTP bits are cleared and the I²C controller becomes a slave receiver.</td>
</tr>
<tr>
<td>NACKIFG</td>
<td>No-acknowledge interrupt. This flag is set when an acknowledge is expected but is not received.</td>
</tr>
<tr>
<td>OAIFG</td>
<td>Own-address interrupt. This flag is set when another master has addressed the I²C module. OAIFG is used in slave mode only.</td>
</tr>
<tr>
<td>ARDYIFG</td>
<td>Register-access-ready interrupt. This flag is set when the previously programmed transfer has completed and the status bits have been updated. This interrupt is used to notify the CPU that the I²C registers are ready to be accessed.</td>
</tr>
<tr>
<td>RXRDYIFG</td>
<td>Receive ready interrupt/status. This flag is set when the I²C module has received new data. RXRDYIFG is automatically cleared when I2CDR is read and the receive buffer is empty. A receiver overrun is indicated if bit I2CRXOVR = 1. RXRDYIFG is used in receive mode only.</td>
</tr>
<tr>
<td>TXRDYIFG</td>
<td>Transmit ready interrupt/status. This flag is set when the I²C module is ready for new transmit data (master transmit mode) or when another master is requesting data (slave transmit mode). TXRDYIFG is automatically cleared when I2CDR and the transmit buffer are full. A transmit underflow is indicated if I2CTXUDF = 1. Unused in receive mode.</td>
</tr>
<tr>
<td>GCIFG</td>
<td>General call interrupt. This flag is set when the I²C module received the general call address (00h). GCIFG is used in receive mode only.</td>
</tr>
<tr>
<td>STTIFG</td>
<td>Start condition detected interrupt. This flag is set when the I²C module detects a start condition while in slave mode. This allows the MSP430 to be in a low power mode with the I²C clock source inactive until a master initiates I²C communication. STTIFG is used in slave mode only.</td>
</tr>
</tbody>
</table>
I2C Module Operation

I2CIV, Interrupt Vector Generator

The I2C interrupt flags are prioritized and combined to source a single interrupt vector. The interrupt vector register I2CIV is used to determine which flag requested an interrupt. The highest priority enabled interrupt generates a number in the I2CIV register that can be evaluated or added to the program counter to automatically enter the appropriate software routine. Disabled I2C interrupts do not affect the I2CIV value. When RXDMAEN = 1, RXRDYIFG will not affect the I2CIV value and when TXDMAEN = 1, TXRDYIFG will not affect the I2CIV value, regardless of the state of RXRDYIE or TXRDYIE.

Any access, read or write, of the I2CIV register automatically resets the highest pending interrupt flag. If another interrupt flag is set, another interrupt is immediately generated after servicing the initial interrupt.

I2CIV Software Example

The following software example shows the recommended use of I2CIV. The I2CIV value is added to the PC to automatically jump to the appropriate routine.

```
I2C_ISR
ADD $I2CIV, PC ; Add offset to jump table

**RXDMAEN**  Bit 7  Receive DMA enable. This bit enables the DMA controller to be used to transfer data from the \(\text{I}^2\text{C}\) module after the \(\text{I}^2\text{C}\) module receives data. When RXDMAEN = 1, RXRDYIE is ignored.

- 0  Disabled
- 1  Enabled

**TXDMAEN**  Bit 6  Transmit DMA enable. This bit enables the DMA controller to be used to provide data to the \(\text{I}^2\text{C}\) module for transmission. When TXDMAEN = 1, TXRDYIE, is ignored.

- 0  Disabled
- 1  Enabled

**I2C**  Bit 5  \(\text{I}^2\text{C}\) mode enable. This bit select \(\text{I}^2\text{C}\) or SPI operation when SYNC = 1.

- 0  SPI mode
- 1  \(\text{I}^2\text{C}\) mode

**XA**  Bit 4  Extended Addressing

- 0  7-bit addressing
- 1  10-bit addressing

**LISTEN**  Bit 3  Listen. This bit selects loopback mode. LISTEN is only valid when MST = 1 and I2CTRX = 1 (master transmitter).

- 0  Normal mode
- 1  SDA is internally fed back to the receiver (loopback).

**SYNC**  Bit 2  Synchronous mode enable

- 0  UART mode
- 1  SPI or \(\text{I}^2\text{C}\) mode

**MST**  Bit 1  Master. This bit selects master or slave mode. The MST bit is automatically cleared when arbitration is lost or a STOP condition is generated.

- 0  Slave mode
- 1  Master mode

**I2CEN**  Bit 0  \(\text{I}^2\text{C}\) enable. The bit enables or disables the \(\text{I}^2\text{C}\) module. The initial condition for this bit is set, and SWRST function for UART or SPI. When the I2C and SYNC bits are first set after a PUC, this bit becomes I2CEN function and is automatically cleared.

- 0  \(\text{I}^2\text{C}\) operation is disabled
- 1  \(\text{I}^2\text{C}\) operation is enabled

Modifyable only when I2CEN = 0

I2CWORD  Bit 7  I2C word mode. Selects byte or word mode for the I2C data register.
0  Byte mode
1  Word mode

I2CRM  Bit 6  I2C repeat mode
0  I2CNDAT defines the number of bytes transmitted.
1  Number of bytes transmitted is controlled by software. I2CNDAT is unused.

I2CSSELx  Bits 5–4  I2C clock source select. When MST = 1 and arbitration is lost, the external SCL signal is automatically used.
00  No clock – I2C module is inactive
01  ACLK
10  SMCLK
11  SMCLK

I2CTRX  Bit 3  I2C transmit. This bit selects the transmit or receive function for the I2C controller when MST = 1. When MST = 0, the R/W bit of the address byte defines the data direction. I2CTRX must be reset for proper slave mode operation.
0  Receive mode. Data is received on the SDA pin.
1  Transmit mode. Data transmitted on the SDA pin.

I2CSTB  Bit 2  Start byte. Setting the I2CSTB bit when MST = 1 initiates a start byte when I2CSTT = 1. After the start byte is initiated, I2CSTB is automatically cleared.
0:  No action
1:  Send START condition and start byte (01h), but no stop condition.

I2CSTP  Bit 1  Stop bit. This bit is used to generate STOP condition. After the stop condition, the I2CSTP is automatically cleared.
0:  No action
1:  Send STOP condition

I2CSTT  Bit 0  Start bit. This bit is used to generate a START condition. After the start condition the I2CSTT is automatically cleared.
0:  No action
1:  Send START condition

Unused Bits
Unused. Always read as 0.

I²C BUSY Bit 5
I²C busy
0 I²C module is idle
1 I²C module is not idle

I²C SCLLOW Bit 4
I²C SCL low. This bit indicates if a slave is holding the SCL line low while the MSP430 is the master and is unused in slave mode.
0 SCL is not being held low
1 SCL is being held low

I²C SBD Bit 3
I²C single byte data. This bit indicates if the receive register I²CDRW holds a word or a byte. I²C SBD is valid only when I²CWORD = 1.
0 A complete word was received
1 Only the lower byte in I²CDR is valid

I²C TXUDF Bit 2
I²C transmit underflow
0 No underflow occurred
1 Transmit underflow occurred

I²C RXOVR Bit 1
I²C receive overrun
0 No receive overrun occurred
1 Receiver overrun occurred

I²C BB Bit 0
I²C bus busy bit. A start condition sets I²C BB to 1. I²C BB is reset by a stop condition or when I²CEN = 0.
0 I²C bus not busy
1 I²C bus busy
### I2C Module Registers

Comparator_A is an analog voltage comparator. This chapter describes Comparator_A. Comparator_A is implemented in MSP430x11x1, MSP430x12x, MSP430x13x, MSP430x14x, MSP430x15x and MSP430x16x devices.

</tbody>
</table>
16.1 Comparator_A Introduction

The comparator_A module supports precision slope analog-to-digital conversions, supply voltage supervision, and monitoring of external analog signals. The Comparator_A block diagram is shown in Figure 16–1.

Features of Comparator_A include:

- Inverting and non-inverting terminal input multiplexer
- Software selectable RC-filter for the comparator output
- Output provided to Timer_A capture input
- Software control of the port input buffer
- Interrupt capability
- Selectable reference voltage generator
- Comparator and reference generator can be powered down
Figure 16–1. Comparator_A Block Diagram
16.2 Comparator_A Operation

The comparator_A module is configured with user software. The setup and operation of comparator_A is discussed in the following sections.

16.2.1 Comparator

The comparator compares the analog voltages at the + and – input terminals. If the + terminal is more positive than the – terminal, the comparator output CAOUT is high. The comparator can be switched on or off using control bit CAON. The comparator should be switched off when not in use to reduce current consumption. When the comparator is switched off, the CAOUT is always low.

16.2.2 Input Analog Switches

The analog input switches connect or disconnect the two comparator input terminals to associated port pins using the P2CAx bits. Both comparator terminal inputs can be controlled individually. The P2CAx bits allow:

- Application of an external signal to the + and – terminals of the comparator
- Routing of an internal reference voltage to an associated output port pin

Internally, the input switch is constructed as a T-switch to suppress distortion in the signal path.

**Note: Comparator Input Connection**

When the comparator is on, the input terminals should be connected to a signal, power, or ground. Otherwise, floating levels may cause unexpected interrupts and increased current consumption.

The CAEX bit controls the input multiplexer, exchanging which input signals are connected to the comparator’s + and – terminals. Additionally, when the comparator terminals are exchanged, the output signal from the comparator is inverted. This allows the user to determine or compensate for the comparator input offset voltage.
16.2.3 Output Filter

The output of the comparator can be used with or without internal filtering. When control bit CAF is set, the output is filtered with an on-chip RC-filter.

Any comparator output oscillates if the voltage difference across the input terminals is small. Internal and external parasitic effects and cross coupling on and between signal lines, power supply lines, and other parts of the system are responsible for this behavior as shown in Figure 16–2. The comparator output oscillation reduces accuracy and resolution of the comparison result. Selecting the output filter can reduce errors associated with comparator oscillation.

Figure 16–2. RC-Filter Response at the Output of the Comparator

16.2.4 Voltage Reference Generator

The voltage reference generator is used to generate $V_{\text{CAREF}}$, which can be applied to either comparator input terminal. The CAREFx bits control the output of the voltage generator. The CARSEL bit selects the comparator terminal to which $V_{\text{CAREF}}$ is applied. If external signals are applied to both comparator input terminals, the internal reference generator should be turned off to reduce current consumption. The voltage reference generator can generate a fraction of the device’s $V_{\text{CC}}$ or a fixed transistor threshold voltage of $\sim 0.55$ V.
16.2.5 Comparator_A, Port Disable Register CAPD

The comparator input and output functions are multiplexed with the associated I/O port pins, which are digital CMOS gates. When analog signals are applied to digital CMOS gates, parasitic current can flow from V\text{CC} to GND. This parasitic current occurs if the input voltage is near the transition level of the gate. Disabling the port pin buffer eliminates the parasitic current flow and therefore reduces overall current consumption.

The CAPD\text{x} bits, when set, disable the corresponding P2 input buffer as shown in Figure 16–3. When current consumption is critical, any P2 pin connected to analog signals should be disabled with their associated CAPD\text{x} bit.

Figure 16–3. Transfer Characteristic and Power Dissipation in a CMOS Inverter/Buffer

![Diagram](image)

16.2.6 Comparator_A Interrupts

One interrupt flag and one interrupt vector are associated with the Comparator_A as shown in Figure 16–4. The interrupt flag CAIFG is set on either the rising or falling edge of the comparator output, selected by the CAIES bit. If both the CAIE and the GIE bits are set, then the CAIFG flag generates an interrupt request. The CAIFG flag is automatically reset when the interrupt request is serviced or may be reset with software.

Figure 16–4. Comparator_A Interrupt System

![Diagram](image)
16.2.7 Comparator_A Used to Measure Resistive Elements

The Comparator_A can be optimized to precisely measure resistive elements using single slope analog-to-digital conversion. For example, temperature can be converted into digital data using a thermistor, by comparing the thermistor’s capacitor discharge time to that of a reference resistor as shown in Figure 16–5. A reference resistor $R_{\text{ref}}$ is compared to $R_{\text{meas}}$.

*Figure 16–5. Temperature Measurement System*

The MSP430 resources used to calculate the temperature sensed by $R_{\text{meas}}$ are:

- Two digital I/O pins to charge and discharge the capacitor.
- I/O set to output high ($V_{\text{CC}}$) to charge capacitor, reset to discharge.
- I/O switched to high-impedance input with CAPDx set when not in use.
- One output charges and discharges the capacitor via $R_{\text{ref}}$.
- One output discharges capacitor via $R_{\text{meas}}$.
- The $+$ terminal is connected to the positive terminal of the capacitor.
- The $-$ terminal is connected to a reference level, for example $0.25 \times V_{\text{CC}}$.
- The output filter should be used to minimize switching noise.
- CAOUT used to gate Timer_A CCI1B, capturing capacitor discharge time.

More than one resistive element can be measured. Additional elements are connected to CA0 with available I/O pins and switched to high impedance when not being measured.
Comparator_A Operation

The thermistor measurement is based on a ratiometric conversion principle. The ratio of two capacitor discharge times is calculated as shown in Figure 16–6.

Figure 16–6. Timing for Temperature Measurement Systems

The $V_{CC}$ voltage and the capacitor value should remain constant during the conversion, but are not critical since they cancel in the ratio:

$$\frac{N_{\text{meas}}}{N_{\text{ref}}} = \frac{-R_{\text{meas}} \times C \times \ln \frac{V_{\text{ref}}}{V_{\text{CC}}}}{-R_{\text{ref}} \times C \times \ln \frac{V_{\text{ref}}}{V_{\text{CC}}}}$$

$$\frac{N_{\text{meas}}}{N_{\text{ref}}} = \frac{R_{\text{meas}}}{R_{\text{ref}}}$$

$$R_{\text{meas}} = R_{\text{ref}} \times \frac{N_{\text{meas}}}{N_{\text{ref}}}$$
16.3 Comparator_A Registers

The Comparator_A registers are listed in Table 16–1:

17.1 ADC12 Introduction

The ADC12 module supports fast, 12-bit analog-to-digital conversions. The module implements a 12-bit SAR core, sample select control, reference generator and a 16 word conversion-and-control buffer. The conversion-and-control buffer allows up to 16 independent ADC samples to be converted and stored without any CPU intervention.

ADC12 features include:

- Greater than 200 ksps maximum conversion rate
- Monotonic 12-bit converter with no missing codes
- Sample-and-hold with programmable sampling periods controlled by software or timers.
- Conversion initiation by software, Timer_A, or Timer_B
- Software selectable on-chip reference voltage generation (1.5 V or 2.5 V)
- Software selectable internal or external reference
- Eight individually configurable external input channels
- Conversion channels for internal temperature sensor, $AV_{CC}$, and external references
- Independent channel-selectable reference sources for both positive and negative references
- Selectable conversion clock source
- Single-channel, repeat-single-channel, sequence, and repeat-sequence conversion modes
- ADC core and reference voltage can be powered down separately
- Interrupt vector register for fast decoding of 18 ADC interrupts
- 16 conversion-result storage registers

The block diagram of ADC12 is shown in Figure 17–1.
Figure 17–1. ADC12 Block Diagram
ADC12 Operation

17.2 ADC12 Operation

The ADC12 module is configured with user software. The setup and operation of the ADC12 is discussed in the following sections.

17.2.1 12-Bit ADC Core

The ADC core converts an analog input to its 12-bit digital representation and stores the result in conversion memory. The core uses two programmable/selectable voltage levels (VR+ and VR−) to define the upper and lower limits of the conversion. The digital output (NADC) is full scale (0FFFh) when the input signal is equal to or higher than VR+, and zero when the input signal is equal to or lower than VR−. The input channel and the reference voltage levels (VR+ and VR−) are defined in the conversion-control memory. The conversion formula for the ADC result NADC is:

\[ N_{ADC} = 4095 \times \frac{V_{in}}{V_{R+} - V_{R-}} \]

The ADC12 core is configured by two control registers, ADC12CTL0 and ADC12CTL1. The core is enabled with the ADC12ON bit. The ADC12 can be turned off when not in use to save power. With few exceptions the ADC12 control bits can only be modified when ENC = 0. ENC must be set to 1 before any conversion can take place.

Conversion Clock Selection

The ADC12CLK is used both as the conversion clock and to generate the sampling period when the pulse sampling mode is selected. The ADC12 source clock is selected using the ADC12SSELx bits and can be divided from 1-8 using the ADC12DIVx bits. Possible ADC12CLK sources are SMCLK, MCLK, ACLK, and an internal oscillator ADC12OSC.

The ADC12OSC, generated internally, is in the 5-MHz range, but varies with individual devices, supply voltage, and temperature. See the device-specific datasheet for the ADC12OSC specification.

The user must ensure that the clock chosen for ADC12CLK remains active until the end of a conversion. If the clock is removed during a conversion, the operation will not complete and any result will be invalid.
17.2.2 ADC12 Inputs and Multiplexer

The eight external and four internal analog signals are selected as the channel for conversion by the analog input multiplexer. The input multiplexer is a break-before-make type to reduce input-to-input noise injection resulting from channel switching as shown in Figure 17–2. The input multiplexer is also a T-switch to minimize the coupling between channels. Channels that are not selected are isolated from the A/D and the intermediate node is connected to analog ground (AVSS) so that the stray capacitance is grounded to help eliminate crosstalk.

The ADC12 uses the charge redistribution method. When the inputs are internally switched, the switching action may cause transients on the input signal. These transients decay and settle before causing errant conversion.

Figure 17–2. Analog Multiplexer

Analog Port Selection

The ADC12 inputs are multiplexed with the port P6 pins, which are digital CMOS gates. When analog signals are applied to digital CMOS gates, parasitic current can flow from VCC to GND. This parasitic current occurs if the input voltage is near the transition level of the gate. Disabling the port pin buffer eliminates the parasitic current flow and therefore reduces overall current consumption. The P6SELx bits provide the ability to disable the port pin input and output buffers.

; P6.0 and P6.1 configured for analog input
BIS.B #3h,&P6SEL ; P6.1 and P6.0 ADC12 function
17.2.3 Voltage Reference Generator

The ADC12 module contains a built-in voltage reference with two selectable voltage levels, 1.5 V and 2.5 V. Either of these reference voltages may be used internally and externally on pin VREF+.

Setting REFON=1 enables the internal reference. When REF2_5V = 1, the internal reference is 2.5 V, the reference is 1.5 V when REF2_5V = 0. The reference can be turned off to save power when not in use.

For proper operation the internal voltage reference generator must be supplied with storage capacitance across VREF+ and AVSS. The recommended storage capacitance is a parallel combination of 10-µF and 0.1-µF capacitors. From turn-on, a maximum of 17 ms must be allowed for the voltage reference generator to bias the recommended storage capacitors. If the internal reference generator is not used for the conversion, the storage capacitors are not required.

**Note: Reference Decoupling**

Approximately 200 µA is required from any reference used by the ADC12 while the two LSBs are being resolved during a conversion. A parallel combination of 10-µF and 0.1-µF capacitors is recommended for any reference used as shown in Figure 17–11.

External references may be supplied for VR+ and VR− through pins VREF+ and VREF−/VeREF− respectively.
17.2.4 Sample and Conversion Timing

An analog-to-digital conversion is initiated with a rising edge of the sample input signal SHI. The source for SHI is selected with the SHSx bits and includes the following:

- The ADC12SC bit
- The Timer_A Output Unit 1
- The Timer_B Output Unit 0
- The Timer_B Output Unit 1

The polarity of the SHI signal source can be inverted with the ISSH bit. The SAMPCON signal controls the sample period and start of conversion. When SAMPCON is high, sampling is active. The high-to-low SAMPCON transition starts the analog-to-digital conversion, which requires 13 ADC12CLK cycles. Two different sample-timing methods are defined by control bit SHP, extended sample mode and pulse mode.

**Extended Sample Mode**

The extended sample mode is selected when SHP = 0. The SHI signal directly controls SAMPCON and defines the length of the sample period $t_{\text{sample}}$. When SAMPCON is high, sampling is active. The high-to-low SAMPCON transition starts the conversion after synchronization with ADC12CLK. See Figure 17–3.

*Figure 17–3. Extended Sample Mode*
Pulse Sample Mode

The pulse sample mode is selected when SHP = 1. The SHI signal is used to trigger the sampling timer. The SHT0x and SHT1x bits in ADC12CTL0 control the interval of the sampling timer that defines the SAMPCON sample period $t_{\text{sample}}$. The sampling timer keeps SAMPCON high after synchronization with AD12CLK for a programmed interval $t_{\text{sample}}$. The total sampling time is $t_{\text{sample}}$ plus $t_{\text{sync}}$. See Figure 17–4.

The SHTx bits select the sampling time in 4x multiples of ADC12CLK. SHT0x selects the sampling time for ADC12MCTL0 to 7 and SHT1x selects the sampling time for ADC12MCTL8 to 15.

Figure 17–4. Pulse Sample Mode
Sample Timing Considerations

When SAMPCON = 0 all Ax inputs are high impedance. When SAMPCON = 1, the selected Ax input can be modeled as an RC low-pass filter during the sampling time $t_{\text{sample}}$, as shown below in Figure 17–5. An internal MUX-on input resistance $R_I$ (max. 2 kΩ) in series with capacitor $C_I$ (max. 40 pF) is seen by the source. The capacitor $C_I$ voltage $V_C$ must be charged to within 1/2 LSB of the source voltage $V_S$ for an accurate 12-bit conversion.

Figure 17–5. Analog Input Equivalent Circuit

The resistance of the source $R_S$ and $R_I$ affect $t_{\text{sample}}$. The following equation can be used to calculate the minimum sampling time $t_{\text{sample}}$ for a 12-bit conversion:

$$t_{\text{sample}} > (R_S + R_I) \times \ln(2^{13}) \times C_I + 800\text{ns}$$

Substituting the values for $R_I$ and $C_I$ given above, the equation becomes:

$$t_{\text{sample}} > (R_S + 2\text{kΩ}) \times 9.011 \times 40\text{pF} + 800\text{ns}$$

For example, if $R_S$ is 10 kΩ, $t_{\text{sample}}$ must be greater than 5.13 μs.
17.2.5 Conversion Memory

There are 16 ADC12MEMx conversion memory registers to store conversion results. Each ADC12MEMx is configured with an associated ADC12MCTLx control register. The SREFx bits define the voltage reference and the INCHx bits select the input channel. The EOS bit defines the end of sequence when a sequential conversion mode is used. A sequence rolls over from ADC12MEM15 to ADC12MEM0 when the EOS bit in ADC12MCTL15 is not set.

The CSTARTADDx bits define the first ADC12MCTLx used for any conversion. If the conversion mode is single-channel or repeat-single-channel the CSTARTADDx points to the single ADC12MCTLx to be used.

If the conversion mode selected is either sequence-of-channels or repeat-sequence-of-channels, CSTARTADDx points to the first ADC12MCTLx location to be used in a sequence. A pointer, not visible to software, is incremented automatically to the next ADC12MCTLx in a sequence when each conversion completes. The sequence continues until an EOS bit in ADC12MCTLx is processed - this is the last control byte processed.

When conversion results are written to a selected ADC12MEMx, the corresponding flag in the ADC12IFGx register is set.

17.2.6 ADC12 Conversion Modes

The ADC12 has four operating modes selected by the CONSEQx bits as discussed in Table 17–1.

<table>
<thead>
<tr>

<td>Repeat-sequence-of-channels</td>
<td>A sequence of channels is converted repeatedly.</td>
</tr>
</tbody>
</table>
Single-Channel Single-Conversion Mode

A single channel is sampled and converted once. The ADC result is written to the ADC12MEMx defined by the CSTARTADDx bits. Figure 17–6 shows the flow of the Single-Channel, Single-Conversion mode. When ADC12SC triggers a conversion, successive conversions can be triggered by the ADC12SC bit. When any other trigger source is used, ENC must be toggled between each conversion.

Figure 17–6. Single-Channel, Single-Conversion Mode

- **Wait for Trigger**
- **x = pointer to ADC12MCTLx**

†Conversion result is unpredictable

\[x = \text{pointer to ADC12MCTLx}\]
ADC12 Operation

Sequence-of-Channels Mode

A sequence of channels is sampled and converted once. The ADC results are written to the conversion memories starting with the ADCMEMx defined by the CSTARTADDx bits. The sequence stops after the measurement of the channel with a set EOS bit. Figure 17–7 shows the sequence-of-channels mode. When ADC12SC triggers a sequence, successive sequences can be triggered by the ADC12SC bit. When any other trigger source is used, ENC must be toggled between each sequence.

Figure 17–7. Sequence-of-Channels Mode
Repeat-Single-Channel Mode

A single channel is sampled and converted continuously. The ADC results are written to the ADC12MEMx defined by the CSTARTADDx bits. It is necessary to read the result after the completed conversion because only one ADC12MEMx memory is used and is overwritten by the next conversion. Figure 17–8 shows repeat-single-channel mode.

Figure 17–8. Repeat-Single-Channel Mode
Repeat-Sequence-of-Channels Mode

A sequence of channels is sampled and converted repeatedly. The ADC results are written to the conversion memories starting with the ADC12MEMx defined by the CSTARTADDx bits. The sequence ends after the measurement of the channel with a set EOS bit and the next trigger signal re-starts the sequence. Figure 17–9 shows the repeat-sequence-of-channels mode.

Figure 17–9. Repeat-Sequence-of-Channels Mode
Using the Multiple Sample and Convert (MSC) Bit

To configure the converter to perform successive conversions automatically and as quickly as possible, a multiple sample and convert function is available. When MSC = 1, CONSEQx > 0, and the sample timer is used, the first rising edge of the SHI signal triggers the first conversion. Successive conversions are triggered automatically as soon as the prior conversion is completed. Additional rising edges on SHI are ignored until the sequence is completed in the single-sequence mode or until the ENC bit is toggled in repeat-single-channel, or repeated-sequence modes. The function of the ENC bit is unchanged when using the MSC bit.

Stopping Conversions

Stopping ADC12 activity depends on the mode of operation. The recommended ways to stop an active conversion or conversion sequence are:

- Resetting ENC in single-channel single-conversion mode stops a conversion immediately and the results are unpredictable. For correct results, poll the busy bit until reset before clearing ENC.
- Resetting ENC during repeat-single-channel operation stops the converter at the end of the current conversion.
- Resetting ENC during a sequence or repeat-sequence mode stops the converter at the end of the sequence.
- Any conversion mode may be stopped immediately by setting the CONSEQx = 0 and resetting ENC bit. Conversion data are unreliable.

Note: No EOS Bit Set For Sequence

If no EOS bit is set and a sequence mode is selected, resetting the ENC bit does not stop the sequence. To stop the sequence, first select a single-channel mode and then reset ENC.
17.2.7 Using the Integrated Temperature Sensor

To use the on-chip temperature sensor, the user selects the analog input channel INCHx = 1010. Any other configuration is done as if an external channel was selected, including reference selection, conversion-memory selection, etc.

The typical temperature sensor transfer function is shown in Figure 17–10. When using the temperature sensor, the sample period must be greater than 30 µs. The temperature sensor offset error can be large, and may need to be calibrated for most applications. See device-specific datasheet for parameters.

Selecting the temperature sensor automatically turns on the on-chip reference generator as a voltage source for the temperature sensor. However, it does not enable the VREF+ output or affect the reference selections for the conversion. The reference choices for converting the temperature sensor are the same as with any other channel.

Figure 17–10. Typical Temperature Sensor Transfer Function

\[ V_{TEMP} = 0.00355(TEMP_C) + 0.986 \]
17.2.8 ADC12 Grounding and Noise Considerations

As with any high-resolution ADC, appropriate printed-circuit-board layout and grounding techniques should be followed to eliminate ground loops, unwanted parasitic effects, and noise.

Ground loops are formed when return current from the A/D flows through paths that are common with other analog or digital circuitry. If care is not taken, this current can generate small, unwanted offset voltages that can add to or subtract from the reference or input voltages of the A/D converter. The connections shown in Figure 17–11 help avoid this.

In addition to grounding, ripple and noise spikes on the power supply lines due to digital switching or switching power supplies can corrupt the conversion result. A noise-free design using separate analog and digital ground planes with a single-point connection is recommend to achieve high accuracy.

Figure 17–11. ADC12 Grounding and Noise Considerations
17.2.9 ADC12 Interrupts

The ADC12 has 18 interrupt sources:

- ADC12IFG0-ADC12IFG15
- ADC12OV, ADC12MEMx overflow
- ADC12TOV, ADC12 conversion time overflow

The ADC12IFGx bits are set when their corresponding ADC12MEMx memory register is loaded with a conversion result. An interrupt request is generated if the corresponding ADC12Ex bit and the GIE bit are set. The ADC12OV condition occurs when a conversion result is written to any ADC12MEMx before its previous conversion result was read. The ADC12TOV condition is generated when another sample-and-conversion is requested before the current conversion is completed.

ADC12IV, Interrupt Vector Generator

All ADC12 interrupt sources are prioritized and combined to source a single interrupt vector. The interrupt vector register ADC12IV is used to determine which enabled ADC12 interrupt source requested an interrupt.

The highest priority enabled ADC12 interrupt generates a number in the ADC12IV register (see register description). This number can be evaluated or added to the program counter to automatically enter the appropriate software routine. Disabled ADC12 interrupts do not affect the ADC12IV value.

Any access, read or write, of the ADC12IV register automatically resets the ADC12OV condition or the ADC12TOV condition if either was the highest pending interrupt. Neither interrupt condition has an accessible interrupt flag. The ADC12IFGx flags are not reset by an ADC12IV access. ADC12IFGx bits are reset automatically by accessing their associated ADC12MEMx register or may be reset with software.

If another interrupt is pending after servicing of an interrupt, another interrupt is generated. For example, if the ADC12OV and ADC12IFG3 interrupts are pending when the interrupt service routine accesses the ADC12IV register, the ADC12OV interrupt condition is reset automatically. After the RETI instruction of the interrupt service routine is executed, the ADC12IFG3 generates another interrupt.
ADC12 Interrupt Handling Software Example

The following software example shows the recommended use of ADC12IV and the handling overhead. The ADC12IV value is added to the PC to automatically jump to the appropriate routine.

The numbers at the right margin show the necessary CPU cycles for each instruction. The software overhead for different interrupt sources includes interrupt latency and return-from-interrupt cycles, but not the task handling itself. The latencies are:

- ADC12IFG0 - ADC12IFG14, ADC12TOV and ADC12OV 16 cycles
- ADC12IFG15 14 cycles

The interrupt handler for ADC12IFG15 shows a way to check immediately if a higher prioritized interrupt occurred during the processing of ADC12IFG15. This saves nine cycles if another ADC12 interrupt is pending.

```asm
; Interrupt handler for ADC12.
INT_ADC12 ; Enter Interrupt Service Routine
ADD &ADC12IV,PC; Add offset to PC
RETI ; Vector 0: No interrupt
JMP ADOV ; Vector 2: ADC overflow
JMP ADTOV ; Vector 4: ADC timing overflow
JMP ADM0 ; Vector 6: ADC12IFG0
... ; Vectors 8-32
JMP ADM14 ; Vector 34: ADC12IFG14

; Handler for ADC12IFG15 starts here. No JMP required.
ADM15 MOV &ADC12MEM15,xxx; Move result, flag is reset
... ; Other instruction needed?
JMP INT_ADC12 ; Check other int pending

; ADC12IFG14-ADC12IFG1 handlers go here

ADM0 MOV &ADC12MEM0,xxx ; Move result, flag is reset
... ; Other instruction needed?
RETI ; Return

ADTOV ... ; Handle Conv. time overflow
RETI ; Return

ADOV ... ; Handle ADCMEMx overflow
RETI ; Return
```

The ADC10 module is a high-performance 10-bit analog-to-digital converter. This chapter describes the ADC10. The ADC10 is implemented in the MSP430x11x2, MSP430x12x2 devices.

18.1 ADC10 Introduction

The ADC10 module supports fast, 10-bit analog-to-digital conversions. The module implements a 10-bit SAR core, sample select control, reference generator, and data transfer controller (DTC).

The DTC allows ADC10 samples to be converted and stored anywhere in memory without CPU intervention. The module can be configured with user software to support a variety of applications.

ADC10 features include:

- Greater than 200 ksps maximum conversion rate
- Monotonic 10-bit converter with no missing codes
- Sample-and-hold with programmable sample periods
- Conversion initiation by software or Timer_A
- Software selectable on-chip reference voltage generation (1.5 V or 2.5 V)
- Software selectable internal or external reference
- Eight external input channels
- Conversion channels for internal temperature sensor, \( V_{CC} \), and external references
- Selectable conversion clock source
- Single-channel, repeated single-channel, sequence, and repeated sequence conversion modes
- ADC core and reference voltage can be powered down separately
- Data transfer controller for automatic storage of conversion results

The block diagram of ADC10 is shown in Figure 18–1.
Figure 18–1. ADC10 Block Diagram
18.2 ADC10 Operation

The ADC10 module is configured with user software. The setup and operation of the ADC10 is discussed in the following sections.

18.2.1 10-Bit ADC Core

The ADC core converts an analog input to its 10-bit digital representation and stores the result in the ADC10MEM register. The core uses two programmable/selectable voltage levels ($V_{R+}$ and $V_{R-}$) to define the upper and lower limits of the conversion. The digital output ($N_{ADC}$) is full scale (03FFh) when the input signal is equal to or higher than $V_{R+}$, and zero when the input signal is equal to or lower than $V_{R-}$. The input channel and the reference voltage levels ($V_{R+}$ and $V_{R-}$) are defined in the conversion-control memory. Conversion results may be in straight binary format or 2s-complement format. The conversion formula for the ADC result when using straight binary format is:

$$N_{ADC} = 1023 \times \frac{V_{in} - V_{R-}}{V_{R+} - V_{R-}}$$

The ADC10 core is configured by two control registers, ADC10CTL0 and ADC10CTL1. The core is enabled with the ADC10ON bit. With few exceptions the ADC10 control bits can only be modified when ENC = 0. ENC must be set to 1 before any conversion can take place.

Conversion Clock Selection

The ADC10CLK is used both as the conversion clock and to generate the sampling period. The ADC10 source clock is selected using the ADC10SSELx bits and can be divided from 1-8 using the ADC10DIVx bits. Possible ADC10CLK sources are SMCLK, MCLK, ACLK and an internal oscillator ADC10OSC.

The ADC10OSC, generated internally, is in the 5-MHz range, but varies with individual devices, supply voltage, and temperature. See the device-specific datasheet for the ADC10OSC specification.

The user must ensure that the clock chosen for ADC10CLK remains active until the end of a conversion. If the clock is removed during a conversion, the operation will not complete, and any result will be invalid.
18.2.2 ADC10 Inputs and Multiplexer

The eight external and four internal analog signals are selected as the channel for conversion by the analog input multiplexer. The input multiplexer is a break-before-make type to reduce input-to-input noise injection resulting from channel switching as shown in Figure 18–2. The input multiplexer is also a T-switch to minimize the coupling between channels. Channels that are not selected are isolated from the A/D and the intermediate node is connected to analog ground (VSS) so that the stray capacitance is grounded to help eliminate crosstalk.

The ADC10 uses the charge redistribution method. When the inputs are internally switched, the switching action may cause transients on the input signal. These transients decay and settle before causing errant conversion.

Figure 18–2. Analog Multiplexer

Analog Port Selection

The ADC10 external inputs A0 to A4 and VREF+ and VREF– share terminals with I/O port P2, which are digital CMOS gates. Optional inputs A5 to A7 are shared on port P3 on selected devices (see device-specific datasheet). When analog signals are applied to digital CMOS gates, parasitic current can flow from VCC to GND. This parasitic current occurs if the input voltage is near the transition level of the gate. Disabling the port pin buffer eliminates the parasitic current flow and therefore reduces overall current consumption. The ADC10AEEx bits provide the ability to disable the port pin input and output buffers.

; P2.3 configured for analog input

18.2.3 Voltage Reference Generator

The ADC10 module contains a built-in voltage reference with two selectable voltage levels, 1.5 V and 2.5 V. Either of these reference voltages may be used internally and externally on pin VREF+. Setting REFON = 1 enables the internal reference. When REF2_5V = 1, the internal reference is 2.5 V, the reference is 1.5 V when REF2_5V = 0.

External references may be supplied for V_{R+} and V_{R-} through pins A4 and A3 respectively.

Low Power Applications

The ADC10 internal voltage reference generator is designed for low power applications, with specific features for a fast startup. For proper operation, an external storage capacitance is not required and has no associated bias time. The total reference turn on time is less than 30 \mu s. Normal power supply decoupling across V_{CC} and V_{SS} using a parallel combination of 10-\mu F and 100-nF capacitors are all that is required.

- When using V_{CC} and V_{SS} as reference voltages, the internal reference should be powered off completely with REFON = 0.
- When using an external reference, the internal reference should be powered off completely. External references may be supplied for V_{R+} and V_{R-} through pins A4 and A3 respectively.
- When the internal reference is used, and the maximum conversion rate is below 50 ksp, setting ADC10SR = 1 reduces the current consumption of the internal reference buffer approximately 50%.
- When both REFOUT = 1 and REFBURST = 1, the reference is present externally only during the sample and conversion period. When REFOUT = 1, and REFBURST = 0 is cleared, the reference voltage is continuously present externally.
18.2.4 Sample and Conversion Timing

An analog-to-digital conversion is initiated with a rising edge of sample input signal SHI. The source for SHI is selected with the SHSx bits and includes the following:

- The ADC10SC bit
- The Timer_A Output Unit 1
- The Timer_A Output Unit 0
- The Timer_A Output Unit 2

The polarity of the SHI signal source can be inverted with the ISSH bit. The SHTx bits select the sample period $t_{sample}$ to be 4, 8, 16, or 64 ADC10CLK cycles. The sampling timer sets SAMPCON high for the selected sample period after synchronization with ADC10CLK. Total sampling time is $t_{sample}$ plus $t_{sync}$. The high-to-low SAMPCON transition starts the analog-to-digital conversion, which requires 13 ADC10CLK cycles as shown in Figure 18–3.

Figure 18–3. Sample Timing
Sample Timing Considerations

When SAMPCON = 0 all Ax inputs are high impedance. When SAMPCON = 1, the selected Ax input can be modeled as an RC low-pass filter during the sampling time \( t_{\text{sample}} \), as shown below in Figure 18–4. An internal MUX-on input resistance \( R_I \) (max. 2 k\( \Omega \)) in series with capacitor \( C_I \) (max. 20 pF) is seen by the source. The capacitor \( C_I \) voltage \( V_C \) must be charged to within \( \frac{1}{2} \) LSB of the source voltage \( V_S \) for an accurate 10-bit conversion.

**Figure 18–4. Analog Input Equivalent Circuit**

![Equivalent Circuit Diagram](image)

The resistance of the source \( R_S \) and \( R_I \) affect \( t_{\text{sample}} \). The following equations can be used to calculate the minimum sampling time \( t_{\text{sample}} \) for a 10-bit conversion.

When ADC10SR = 0:

\[
 t_{\text{sample}} > (R_S + R_I) \times \ln(2^{11}) \times C_I + 800\text{ns}
\]

When ADC10SR = 1:

\[
 t_{\text{sample}} > (R_S + R_I) \times \ln(2^{11}) \times C_I + 2.5\mu\text{s}
\]

Substituting the values for \( R_I \) and \( C_I \) given above, the equation becomes:

\[
 t_{\text{sample}} > (R_S + 2k) \times 7.625 \times 20\text{pF} + 800\text{ns} \quad \text{(ADC10SR = 0)}
\]

\[
 t_{\text{sample}} > (R_S + 2k) \times 7.625 \times 20\text{pF} + 2.5\mu\text{s} \quad \text{(ADC10SR = 1)}
\]

For example, if \( R_S \) is 10 k\( \Omega \), \( t_{\text{sample}} \) must be greater than 2.63 \( \mu\text{s} \) when ADC10SR = 0, or 4.33 \( \mu\text{s} \) when ADC10SR = 1.
18.2.5 Conversion Modes

The ADC10 has four operating modes selected by the CONSEQx bits as discussed in Table 18–1.

Table 18–1. Conversion Mode Summary

<table>
<thead>
<tr>
<th>CONSEQx</th>
<th>Mode</th>
<th>Operation</th>

<tr>
<td>11</td>
<td>Repeat sequence-of-channels</td>
<td>A sequence of channels is converted repeatedly.</td>
</tr>
</tbody>
</table>
Single-Channel Single-Conversion Mode

A single channel selected by INCHx is sampled and converted once. The ADC result is written to ADC10MEM. Figure 18–5 shows the flow of the single-channel, single-conversion mode. When ADC10SC triggers a conversion, successive conversions can be triggered by the ADC10SC bit. When any other trigger source is used, ENC must be toggled between each conversion.

Figure 18–5. Single-Channel Single-Conversion Mode

x = input channel Ax
† Conversion result is unpredictable
Sequence-of-Channels Mode

A sequence of channels is sampled and converted once. The sequence begins with the channel selected by INCHx and decrements to channel A0. Each ADC result is written to ADC10MEM. The sequence stops after conversion of channel A0. Figure 18–6 shows the sequence-of-channels mode. When ADC10SC triggers a sequence, successive sequences can be triggered by the ADC10SC bit. When any other trigger source is used, ENC must be toggled between each sequence.

\[ (4/8/16/64) \times \text{ADC10CLK} \]
\[ x = 0 \]
\[ \text{Sample, Input Channel Ax} \]
\[ \text{MSC} = 1 \text{ and } x \neq 0 \]
\[ 12 \times \text{ADC10CLK} \]
\[ 1 \times \text{ADC10CLK} \]
\[ \text{Convert} \]
\[ \text{Conversion Completed, Result to ADC10MEM, ADC10IFG is Set} \]
\[ x = \text{input channel Ax} \]
Repeat-Single-Channel Mode

A single channel selected by INCHx is sampled and converted continuously. Each ADC result is written to ADC10MEM. Figure 18–7 shows the repeat-single-channel mode.

Figure 18–7. Repeat-Single-Channel Mode
Repeat-Sequence-of-Channels Mode

A sequence of channels is sampled and converted repeatedly. The sequence begins with the channel selected by INCHx and decrements to channel A0. Each ADC result is written to ADC10MEM. The sequence ends after conversion of channel A0, and the next trigger signal re-starts the sequence. Figure 18–8 shows the repeat-sequence-of-channels mode.

Using the MSC Bit

To configure the converter to perform successive conversions automatically and as quickly as possible, a multiple sample and convert function is available. When MSC = 1 and CONSEQx > 0 the first rising edge of the SHI signal triggers the first conversion. Successive conversions are triggered automatically as soon as the prior conversion is completed. Additional rising edges on SHI are ignored until the sequence is completed in the single-sequence mode or until the ENC bit is toggled in repeat-single-channel, or repeated-sequence modes. The function of the ENC bit is unchanged when using the MSC bit.

Stopping Conversions

Stopping ADC10 activity depends on the mode of operation. The recommended ways to stop an active conversion or conversion sequence are:

- Resetting ENC in single-channel single-conversion mode stops a conversion immediately and the results are unpredictable. For correct results, poll the ADC10BUSY bit until reset before clearing ENC.
- Resetting ENC during repeat-single-channel operation stops the converter at the end of the current conversion.
- Resetting ENC during a sequence or repeat sequence mode stops the converter at the end of the sequence.
- Any conversion mode may be stopped immediately by setting the CONSEQx=0 and resetting the ENC bit. Conversion data is unreliable.
18.2.6 ADC10 Data Transfer Controller

The ADC10 includes a data transfer controller (DTC) to automatically transfer conversion results from ADC10MEM to other on-chip memory locations. The DTC is enabled by setting the ADC10DTC1 register to a nonzero value.

When the DTC is enabled, each time the ADC10 completes a conversion and loads the result to ADC10MEM, a data transfer is triggered. No software intervention is required to manage the ADC10 until the predefined amount of conversion data has been transferred. Each DTC transfer requires one CPU MCLK. To avoid any bus contention during the DTC transfer, the CPU is halted, if active, for the one MCLK required for the transfer.

A DTC transfer must not be initiated while the ADC10 is busy. Software must ensure that no active conversion or sequence is in progress when the DTC is configured:

```
; ADC10 activity test
   BIC.W #ENC,&ADC10CTL0 ;
busy_test BIT.W #BUSY,&ADC10CTL1;
   JNZ busy_test ;
   MOV.W #xxx,&ADC10SA ; Safe
   MOV.B #xx,&ADC10DTC1 ;
; continue setup
```
ADC10 Operation

One-Block Transfer Mode

The one-block mode is selected if the ADC10TB is reset. The value n in ADC10DTC1 defines the total number of transfers for a block. The block start address is defined anywhere in the MSP430 address range using the 16-bit register ADC10SA. The block ends at ADC10SA+2n–2. The one-block transfer mode is shown in Figure 18–9.

**Figure 18–9. One-Block Transfer**

![Diagram of One-Block Transfer](image)

The internal address pointer is initially equal to ADC10SA and the internal transfer counter is initially equal to ‘n’. The internal pointer and counter are not visible to software. The DTC transfers the word-value of ADC10MEM to the address pointer ADC10SA. After each DTC transfer, the internal address pointer is incremented by two and the internal transfer counter is decremented by one.

The DTC transfers continue with each loading of ADC10MEM, until the internal transfer counter becomes equal to zero. No additional DTC transfers will occur until a write to ADC10SA. When using the DTC in the one-block mode, the ADC10IFG flag is set only after a complete block has been transferred. Figure 18–10 shows a state diagram of the one-block mode.
Figure 18–10. State Diagram for Data Transfer Control in One-Block Transfer Mode

  - Write to ADC10SA
  - or
  - n = 0

- **Synchronize with MCLK**
  - x > 0

- **1 x MCLK cycle**

- **n is latched in counter ‘x’**
Two-Block Transfer Mode

The two-block mode is selected if the ADC10TB bit is set. The value \( n \) in ADC10DTC1 defines the number of transfers for one block. The address range of the first block is defined anywhere in the MSP430 address range with the 16-bit register ADC10SA. The first block ends at \( ADC10SA + 2n - 2 \). The address range for the second block is defined as \( SA + 2n \) to \( SA + 4n - 2 \). The two-block transfer mode is shown in Figure 18–11.

The internal address pointer is initially equal to ADC10SA and the internal transfer counter is initially equal to \( n \). The internal pointer and counter are not visible to software. The DTC transfers the word-value of ADC10MEM to the address pointer ADC10SA. After each DTC transfer the internal address pointer is incremented by two and the internal transfer counter is decremented by one.

The DTC transfers continue, with each loading of ADC10MEM, until the internal transfer counter becomes equal to zero. At this point, block one is full and both the ADC10IFG flag the ADC10B1 bit are set. The user can test the ADC10B1 bit to determine that block one is full.

The DTC continues with block two. The internal transfer counter is automatically reloaded with \( n \). At the next load of the ADC10MEM, the DTC begins transferring conversion results to block two. After \( n \) transfers have completed, block two is full. The ADC10IFG flag is set and the ADC10B1 bit is cleared. User software can test the cleared ADC10B1 bit to determine that block two is full. Figure 18–12 shows a state diagram of the two-block mode.

### ADC10 Operation

#### Continuous Transfer

A continuous transfer is selected if ADC10CT bit is set. The DTC will not stop after block one in (one-block mode) or block two (two-block mode) has been transferred. The internal address pointer and transfer counter are set equal to ADC10SA and n respectively. Transfers continue starting in block one. If the ADC10CT bit is reset, DTC transfers cease after the current completion of transfers into block one (in the one-block mode) or block two (in the two-block mode) have been transfer.

#### DTC Transfer Cycle Time

For each ADC10MEM transfer, the DTC requires one or two MCLK clock cycles to synchronize, one for the actual transfer (while the CPU is halted), and one cycle of wait time. Because the DTC uses MCLK, the DTC cycle time is dependent on the MSP430 operating mode and clock system setup.

If the MCLK source is active, but the CPU is off, the DTC uses the MCLK source for each transfer, without re-enabling the CPU. If the MCLK source is off, the DTC temporarily restarts MCLK, sourced with DCOCLK, only during a transfer. The CPU remains off and after the DTC transfer, MCLK is again turned off. The maximum DTC cycle time for all operating modes is shown in Table 18–2.

#### Table 18–2. Maximum DTC Cycle Time

<table>
<thead>
<tr>
<th>CPU Operating Mode</th>
<th>Clock Source</th>
<th>Maximum DTC Cycle Time</th>

</tr>
<tr>
<td>Low-power mode LPM4</td>
<td>MCLK=LFXT1CLK</td>
<td>4 MCLK cycles + 6 μs†</td>
</tr>
</tbody>
</table>

† The additional 6 μs are needed to start the DCOCLK. It is the \( t_{\text{LPMx}} \) parameter in the datasheet.
18.2.7 Using the Integrated Temperature Sensor

To use the on-chip temperature sensor, the user selects the analog input channel INCHx = 1010. Any other configuration is done as if an external channel was selected, including reference selection, conversion-memory selection, etc.

The typical temperature sensor transfer function is shown in Figure 18–13. When using the temperature sensor, the sample period must be greater than 30 µs. The temperature sensor offset error can be large, and may need to be calibrated for most applications. See the device-specific datasheet for the parameters.

Selecting the temperature sensor automatically turns on the on-chip reference generator as a voltage source for the temperature sensor. However, it does not enable the VREF+ output or affect the reference selections for the conversion. The reference choices for converting the temperature sensor are the same as with any other channel.

*Figure 18–14. Typical Temperature Sensor Transfer Function*
18.2.8 ADC10 Grounding and Noise Considerations

As with any high-resolution ADC, appropriate printed-circuit-board layout and grounding techniques should be followed to eliminate ground loops, unwanted parasitic effects, and noise.

Ground loops are formed when return current from the A/D flows through paths that are common with other analog or digital circuitry. If care is not taken, this current can generate small, unwanted offset voltages that can add to or subtract from the reference or input voltages of the A/D converter. The connections shown in Figure 18–15 help avoid this.

In addition to grounding, ripple and noise spikes on the power supply lines due to digital switching or switching power supplies can corrupt the conversion result. A noise-free design is important to achieve high accuracy.

Figure 18–16. ADC10 Grounding and Noise Considerations
18.2.9 ADC10 Interrupts

One interrupt and one interrupt vector are associated with the ADC10 as shown in Figure 18–17. When the DTC is not used (ADC10DTC1 = 0) ADC10IFG is set when conversion results are loaded into ADC10MEM. When DTC is used (ADC10DTC1 > 0) ADC10IFG is set when a block transfer completes and the internal transfer counter 'n' = 0. If both the ADC10IE and the GIE bits are set, then the ADC10IFG flag generates an interrupt request. The ADC10IFG flag is automatically reset when the interrupt request is serviced or may be reset by software.

*Figure 18–17. ADC10 Interrupt System*
18.3 ADC10 Registers

The ADC10 registers are listed in Table 18–3.

ADC10SAx Bits 15-1  
- ADC10 start address. These bits are the start address for the DTC. A write to register ADC10SA is required to initiate DTC transfers.
The DAC12 module is a 12-bit, voltage output digital-to-analog converter. This chapter describes the DAC12. Two DAC12 modules are implemented in the MSP430x15x and MSP430x16x devices.
19.1 DAC12 Introduction

The DAC12 module is a 12-bit, voltage output DAC. The DAC12 can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. When multiple DAC12 modules are present, they may be grouped together for synchronous update operation.

Features of the DAC12 include:

- 12-bit monotonic output
- 8- or 12-bit voltage output resolution
- Programmable settling time vs power consumption
- Internal or external reference selection
- Straight binary or 2's compliment data format
- Self-calibration option for offset correction
- Synchronized update capability for multiple DAC12s

Note: Multiple DAC12 Modules

Some devices may integrate more than one DAC12 module. In the case where more than one DAC12 is present on a device, the multiple DAC12 modules operate identically.

Throughout this chapter, nomenclature appears such as DAC12_xDAT or DAC12_xCTL to describe register names. When this occurs, the x is used to indicate which DAC12 module is being discussed. In cases where operation is identical, the register is simply referred to as DAC12_xCTL.

The block diagram of the two DAC12 modules in the MSP430F15x/16x devices is shown in Figure 19–1.
Figure 19–1. DAC12 Block Diagram

- $V_{\text{REF}^+}$ 2.5V or 1.5V reference from ADC12
- $\text{DAC12}_0\text{DAT}$ Updated
- $\text{DAC12}_0\text{Latch}$
- $\text{DAC12}_0\text{OUT}$
- $\text{DAC12}_1\text{DAT}$ Updated
- $\text{DAC12}_1\text{OUT}$
- $\text{DAC12}_1\text{Latch}$
- 3x3 DAC12RES
- 3x3 DAC12DF
- 3x3 DAC12IR
19.2 DAC12 Operation

The DAC12 module is configured with user software. The setup and operation of the DAC12 is discussed in the following sections.

19.2.1 DAC12 Core

The DAC12 can be configured to operate in 8- or 12-bit mode using the DAC12RES bit. The full-scale output is programmable to be 1x or 3x the selected reference voltage via the DAC12IR bit. This feature allows the user to control the dynamic range of the DAC12. The DAC12DF bit allows the user to select between straight binary data and 2’s compliment data for the DAC. When using straight binary data format, the formula for the output voltage is given in Table 19–1.

Table 19–1. DAC12 Full-Scale Range (Vref = V_{eREF+} or V_{REF+})

<table>
<thead>
<tr>
<th>Resolution</th>
<th>DAC12RES</th>
<th>DAC12IR</th>
<th>Output Voltage Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>12 bit</td>
<td>0</td>
<td>0</td>
<td>( V_{out} = \frac{V_{ref} \times 3 \times DAC12_x_DAT}{4096} )</td>
</tr>
<tr>
<td>12 bit</td>
<td>0</td>
<td>1</td>
<td>( V_{out} = \frac{V_{ref} \times DAC12_x_DAT}{4096} )</td>
</tr>
<tr>
<td>8 bit</td>
<td>1</td>
<td>0</td>
<td>( V_{out} = \frac{V_{ref} \times 3 \times DAC12_x_DAT}{256} )</td>
</tr>
<tr>
<td>8 bit</td>
<td>1</td>
<td>1</td>
<td>( V_{out} = \frac{V_{ref} \times DAC12_x_DAT}{256} )</td>
</tr>
</tbody>
</table>

In 8-bit mode the maximum useable value for DAC12_xDAT is 0FFh and in 12-bit mode the maximum useable value for DAC12_xDAT is 0FFFh. Values greater than these may be written to the register, but all leading bits are ignored.

DAC12 Port Selection

The DAC12 outputs are multiplexed with the port P6 pins and ADC12 analog inputs. When DAC12AMPx > 0, the DAC12 function is automatically selected for the pin, regardless of the state of the associated P6SELx and P6DIRx bits.
19.2.2 DAC12 Reference

The reference for the DAC12 is configured to use either an external reference voltage or the internal 1.5-V/2.5-V reference from the ADC12 module with the DAC12SREFX bits. When DAC12SREFX = {0,1} the VRREF+ signal is used as the reference and when DAC12SREFX = {2,3} the VREF+ signal is used as the reference.

To use the ADC12 internal reference, it must be enabled and configured via the applicable ADC12 control bits (see the ADC12 chapter). Once the ADC12 reference is configured, the reference voltage appears on the VRREF+ signal.

DAC12 Reference Input and Voltage Output Buffers

The reference input and voltage output buffers of the DAC12 can be configured for optimized settling time vs power consumption. Eight combinations are selected using the DAC12AMPX bits. In the low/low setting, the settling time is the slowest, and the current consumption of both buffers is the lowest. The medium and high settings have faster settling times, but the current consumption increases. See the device-specific data sheet for parameters.

19.2.3 Updating the DAC12 Voltage Output

The DAC12_xDAT register can be connected directly to the DAC12 core or double buffered. The trigger for updating the DAC12 voltage output is selected with the DAC12LSElx bits.

When DAC12LSElx = 0 the data latch is transparent and the DAC12_xDAT register is applied directly to the DAC12 core. the DAC12 output updates immediately when new DAC12 data is written to the DAC12_xDAT register, regardless of the state of the DAC12ENC bit.

When DAC12LSElx = 1, DAC12 data is latched and applied to the DAC12 core after new data is written to DAC12_xDAT. When DAC12LSElx = 2 or 3, data is latched on the rising edge from the Timer_A CCR1 output or Timer_B CCR2 output respectively. DAC12ENC must be set to latch the new data when DAC12LSElx > 0.
19.2.4 DAC12_xDAT Data Format

The DAC12 supports both straight binary and 2’s compliment data formats. When using straight binary data format, the full-scale output value is 0FFFh in 12-bit mode (0FFh in 8-bit mode) as shown in Figure 19–2.

Figure 19–2. Output Voltage vs DAC12 Data, 12-Bit, Straight Binary Mode

When using 2’s compliment data format, the range is shifted such that a DAC12_xDAT value of 0800h (0080h in 8-bit mode) results in a zero output voltage, 0000h is the mid-scale output voltage, and 07FFh (007Fh for 8-bit mode) is the full-scale voltage output as shown in Figure 19–3.

Figure 19–3. Output Voltage vs DAC12 Data, 12-Bit, 2’s Compliment Mode
19.2.5 DAC12 Output Amplifier Offset Calibration

The offset voltage of the DAC12 output amplifier can be positive or negative. When the offset is negative, the output amplifier attempts to drive the voltage negative, but cannot do so. The output voltage remains at zero until the DAC12 digital input produces a sufficient positive output voltage to overcome the negative offset voltage, resulting in the transfer function shown in Figure 19–4.

*Figure 19–4. Negative Offset*

When the output amplifier has a positive offset, a digital input of zero does not result in a zero output voltage. The DAC12 output voltage reaches the maximum output level before the DAC12 data reaches the maximum code. This is shown in Figure 19–5.

*Figure 19–5. Positive Offset*

The DAC12 has the capability to calibrate the offset voltage of the output amplifier. Setting the DAC12CALON bit initiates the offset calibration. The calibration should complete before using the DAC12. When the calibration is complete, the DAC12CALON bit is automatically reset. The DAC12AMPx bits should be configured before calibration. For best calibration results, port and CPU activity should be minimized during calibration.
19.2.6 Grouping Multiple DAC12 Modules

Multiple DAC12s can be grouped together with the DAC12GRP bit to synchronize the update of each DAC12 output. Hardware ensures that all DAC12 modules in a group update simultaneously independent of any interrupt or NMI event.

On the MSP430x15x and MSP430x16x devices, DAC12_0 and DAC12_1 are grouped by setting the DAC12GRP bit of DAC12_0. The DAC12GRP bit of DAC12_1 is don’t care. When DAC12_0 and DAC12_1 are grouped:

- The DAC12_1 DAC12LSELx bits select the update trigger for both DACs
- The DAC12LSELx bits for both DACs must be > 0
- The DAC12ENC bits of both DACs must be set to 1

When DAC12_0 and DAC12_1 are grouped, both DAC12_xDAT registers must be written to before the outputs update - even if data for one or both of the DACs is not changed. Figure 19–6 shows a latch-update timing example for grouped DAC12_0 and DAC12_1.

When DAC12_0 DAC12GRP = 1 and both DAC12_x DAC12LSELx > 0 and either DAC12ENC = 0, neither DAC12 will update.

Figure 19–6. DAC12 Group Update Example, Timer_A3 Trigger

Note: DAC12 Settling Time

The DMA controller is capable of transferring data to the DAC12 faster than the DAC12 output can settle. The user must assure the DAC12 settling time is not violated when using the DMA controller. See the device-specific data sheet for parameters.
19.2.7 DAC12 Interrupts

The DAC12 interrupt vector is shared with the DMA controller. Software must check the DAC12IFG and DMAIFG flags to determine the source of the interrupt.

The DAC12IFG bit is set when DAC12LSELx > 0 and DAC12 data is latched from the DAC12_xDAT register into the data latch. When DAC12LSELx = 0, the DAC12IFG flag is not set.

A set DAC12IFG bit indicates that the DAC12 is ready for new data. If both the DAC12IE and GIE bits are set, the DAC12IFG generates an interrupt request. The DAC12IFG flag is not reset automatically. It must be reset by software.
### 19.3 DAC12 Registers

The DAC12 registers are listed in Table 19–2:

#### DAC12 Data Bits 11-0

- **DAC12 Data**
  - **Bits 11-0**: DAC12 data

#### DAC12 Data Format

<table>
<thead>
<tr>
<th>DAC12 Data Format</th>
<th>DAC12 Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>12-bit binary</td>
<td>The DAC12 data are right-justified. Bit 11 is the MSB.</td>
</tr>
<tr>
<td>12-bit 2's complement</td>
<td>The DAC12 data are right-justified. Bit 11 is the MSB (sign).</td>
</tr>
<tr>
<td>8-bit binary</td>
<td>The DAC12 data are right-justified. Bit 7 is the MSB. Bits 11-8 are don’t care and do not effect the DAC12 core.</td>
</tr>
<tr>
<td>8-bit 2's complement</td>
<td>The DAC12 data are right-justified. Bit 7 is the MSB (sign). Bits 11-8 are don’t care and do not effect the DAC12 core.</td>
</tr>
</tbody>
</table>

#### Unused Bits 15-12

- **Unused**: These bits are always 0 and do not affect the DAC12 core.
